Effective-One-Body approach to the general relativistic 2-body dynamics

Alessandro Nagar

INFN (Italy) and IHES (France)

in collaboration with T. Damour (IHES)

Basic reference: T. Damour, "Introductory lectures on the Effective One Body formalism", arXiv: 0802.4047

Introduce the problem: detect Gravitational Waves

A network of ground-based interferometric gravitational wave (GW) detectors (LIGO/VIRGO/GEO) is now taking data near its planned sensitivity.

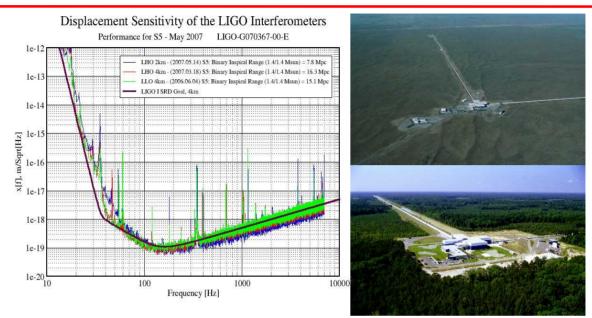

Coalescing (stellar-mass, M~30M_{sun}.) binary black hole systems (BBHs) are among the most promising GW sources for these detectors.

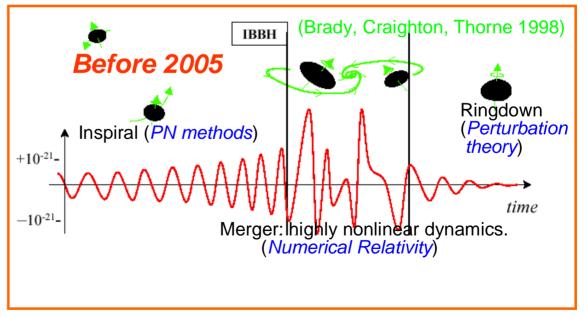

Most useful part of the waveform is emitted in the last 5 orbits of the inspiral and during the plunge that takes place after the crossing of the Last Stable Orbit (LSO).

To successfully detect GWs fromBBHs coalescence one *needs to know in advance* the shape of the signal

Detection and data analysis is made by means of *templates* that accurately represent the gravitational waveforms emitted by the source.

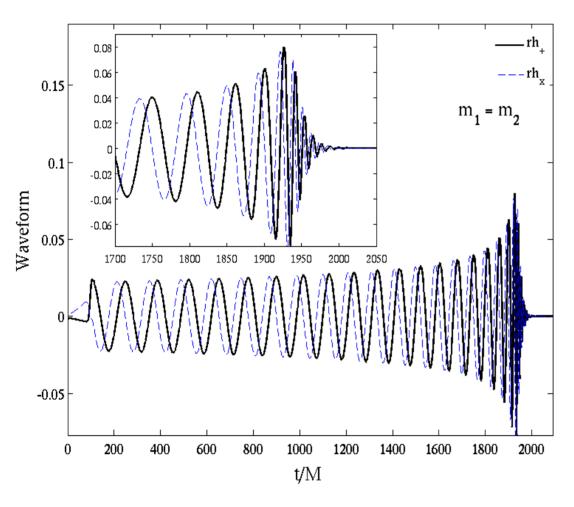

State-of-the-art Numerical Relativity (NR) simulations can now merge black-holes, but are not sufficiently efficient to densely sample the parameter space. One needs analytical methods to produce thousands of templates (possibly in real time).

The binary black hole (BBH) coalescence process

■ F. Pretorius (Princeton, Phys.Rev.Lett. 95 (2005) 121101)

- The BBH coalescence problem (for comparable masses) has been studied numerically until the mid 90s.
- •Numerical Relativity (NR) solves Einstein's equations numerically on supercomputers.
- In 2005, *Frans Pretorius* made the breakthrough, being the first to compute the merger of two (non-spinning) BHs
- •All the others NR groups followed: many important results (kicks, spin, different mass ratios, three-BHs evolutions...)
- Nowadays, computation of inspiralling and merging (spinning) BHs has become almost everyday routine.
- The computational cost is still huge for template banks-building purposes!

Aim of EOB formalism

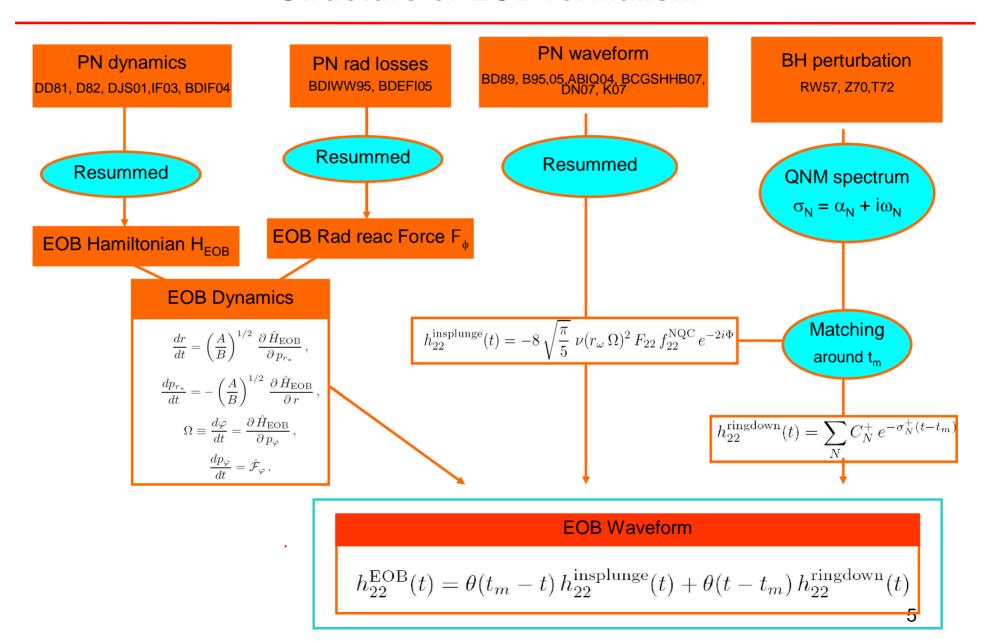

- To provide an *accurate analytical* description of the motion and radiation of binary black holes, which covers inspiral, plunge, merger and ringdown
- Idea: to extend the domain of validity of perturbation theory (PN, BH-pert) so as to approximately cover non-perturbative features
- (Expected) Utility of EOB formalism:

provide accurate GW templates for the multi-parameter space $(m_1, m_2, S_1, S_2,...)$ which is difficult to densely cover with NR

gives us a physical understanding of dynamics and radiation

can be extended to BH-NS or NS-NS systems up to tidal disruption.

Structure of EOB formalism

Historical roots of EOB

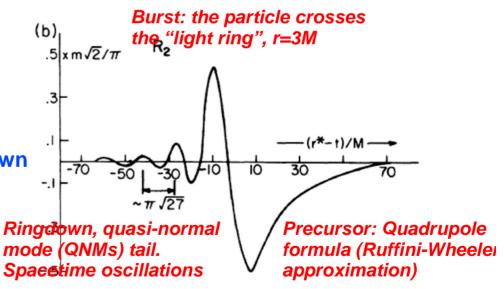

•H_{EOB}: Quantum Hamiltonian H(I_a) [Sommerfeld 1916, Damour-Schäfer 1988]
QED positronium states [Brezin, Itzykson, Zinn-Justin 1970]

F_φ: Padé resummation [DIS 1998]

h(t): [Davis, Ruffini, Tiomno 1972] CLAP [Price-Pullin 1994]

Discovery of the structure:

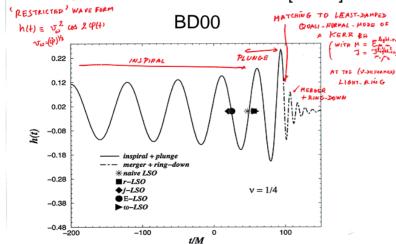

Precursor (plunge)-Burst (merger)-Ringdown

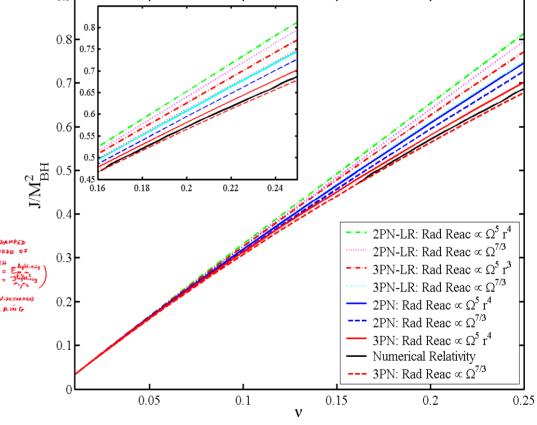

Successful predictions from EOB

- i. Importance of nonadiabatic effects at the end of inspiral
- ii. Blurred transition from inspiral to a "plunge" that is just a smooth continuation of the inspiral
- iii. First estimate of a complete GW waveform [BD00]
- iV. Estimates of the radiated energy and of the spin of the final black hole, e.g. J/M² ~ 0.795 [2PN, LSO, BD00]; 0.77 [3PN, >LSO, BCD06]
- V. Parallel spins imply larger radiated energy (tighter orbits), and J/M² <1 [D01,BCD06]

Vi. Qualitative recoil versus time [DG06]

Damour, Nagar, PRD 76, 044003 (2007)

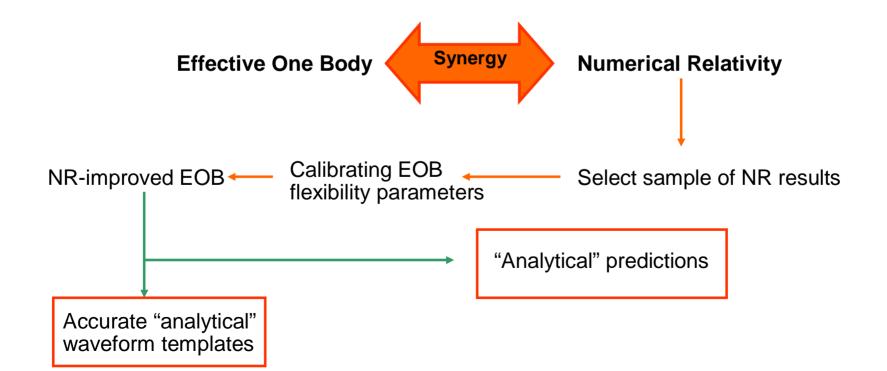

Flexibility of EOB

However, the EOB approach, far from being a rigid structure, is extremely flexible. One can modify the basic functions [such as A(u) | determining the EOB dynamics by introducing new parameters corresponding to (yet) uncalculated higher PN effects. These terms become important only for orbits closer than 6GM, and/or for fast-spinning holes. Therefore, when either higher-accuracy analytical calculations are performed or numerical relativity becomes able to give physically relevant data about the interaction of (fast-spinning) black holes, we expect that it will be possible to complete the current EOB Hamiltonian so as to incorporate this information. As the parameter space of two spinning black holes (with arbitrarily oriented spins) is very large, numerical relativity will never be able, by itself, to cover it densely. We think, however, that a suitable "numerically fitted" (and, if possible, "analytically extended") EOB Hamiltonian should be able to fit the needs of upcoming GW detectors. (Damour 2001)

EOB flexibility parameters

- a_5 [a.k.a. $a_5(v)$, b_5 , λ , a_5^1](D01, DGG02)
- [■]v_{pole}, a_{RR},... (DIJS03)
- a,b: non-quasi-circular corrections to waveform (DN07a, DN07b)
- •p,δ: matching "comb" (DN07a)

Defining H_{EOB} by thinking quantum-mechanically (Wheeler)

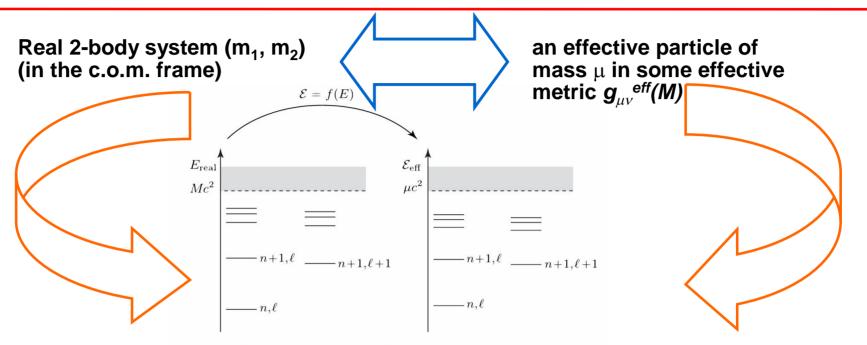

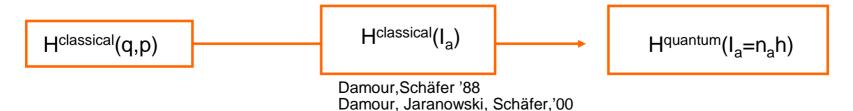

Figure 1: Sketch of the correspondence between the quantized energy levels of the real and effective conservative dynamics. n denotes the 'principal quantum

Sommerfeld "Old Quantum Mechanics":

$$J = \ell \hbar = \frac{1}{2\pi} \oint p_{\varphi} d\varphi$$

$$N = n\hbar = I_r + J$$

$$I_r = \frac{1}{2\pi} \oint p_r dr = I_r + J$$

2-body Taylor-expanded 3PN Hamiltonian [JS98, DJS00,01]

$$\begin{split} H(\mathbf{x}_{a},\mathbf{p}_{a}) &= \sum_{a} m_{a}c^{2} + H_{N}(\mathbf{x}_{a},\mathbf{p}_{a}) + \frac{1}{c^{2}}H_{1PN}(\mathbf{x}_{a},\mathbf{p}_{a}) + \frac{1}{c^{4}}H_{2PN}(\mathbf{x}_{a},\mathbf{p}_{a}) + \frac{1}{c^{6}}H_{3PN}(\mathbf{x}_{a},\mathbf{p}_{a}) + \mathcal{O}\left(\frac{1}{c^{8}}\right) \\ H_{N}(\mathbf{x}_{a},\mathbf{p}_{a}) &= \sum_{a} \frac{\mathbf{p}_{a}^{2}}{2m_{a}} - \frac{1}{2}\sum_{a}\sum_{b\neq a} \frac{Gm_{a}m_{b}}{r_{ab}} \\ H_{1PN}(\mathbf{x}_{a},\mathbf{p}_{a}) &= -\frac{1}{8}\frac{(\mathbf{p}_{1}^{2})^{2}}{r^{2}} + \frac{1}{8}\frac{Gm_{1}m_{2}}{r_{12}} \left[-12\frac{\mathbf{p}_{1}^{2}}{m_{1}^{2}} + 14\frac{(\mathbf{p}_{1}\cdot\mathbf{p}_{2})}{m_{1}^{2}} + 2\frac{(\mathbf{n}_{12}\cdot\mathbf{p}_{1})(\mathbf{n}_{12}\cdot\mathbf{p}_{2})}{m_{1}^{2}m_{2}^{2}} \right] \\ &+ \frac{1}{4}\frac{Gm_{1}m_{2}}{r_{12}}\frac{G(m_{1}+m_{2})}{r_{12}} + (1-2). \end{split}$$

(12)

The 2-body Hamiltonian [at 2PN for clarity]

The 2-body Hamiltonian in the c.o.m frame at 2PN:

$$H_{\mathrm{2PN}}^{\mathrm{relative}}(\boldsymbol{q}, \boldsymbol{p}) = H_0(\boldsymbol{q}, \boldsymbol{p}) + \frac{1}{c^2} H_2(\boldsymbol{q}, \boldsymbol{p}) + \frac{1}{c^4} H_4(\boldsymbol{q}, \boldsymbol{p})$$

Rewrite the c.o.m. energy using *action variables* (à la Sommerfeld): obtain the "quantum" energy levels [from Damour&Schaefer 1988]

$$\begin{split} E_{\text{2PN}}^{\text{relative}}(n,\ell) = & \left(-\frac{1}{2} \, \mu \, \frac{\alpha^2}{n^2} \, \right) \! 1 + \frac{\alpha^2}{c^2} \left(\frac{c_{11}}{n\ell} + \frac{c_{20}}{n^2} \right) \\ & + \frac{\alpha^4}{c^4} \left(\frac{c_{13}}{n\ell^3} + \frac{c_{22}}{n^2\ell^2} + \frac{c_{31}}{n^3\ell} + \frac{c_{40}}{n^4} \right) \, \right] \quad \text{``Delaunay Hamiltonian''} \end{split}$$
 "Balmer" formula

- •Dependence on $u \equiv \mu/M$
- PN correction: open orbits
- Degeneracy removed

$$J = \ell \hbar = \frac{1}{2\pi} \oint p_{\varphi} d\varphi$$

$$N = n\hbar = I_r + J$$

$$I_r = \frac{1}{2\pi} \oint p_r dr$$

$$\alpha \equiv GM\mu/\hbar = G m_1 m_2/\hbar$$

Dictionary between real and effective dynamics

•Unknowns: μ , M, f(E), $g_{\mu\nu}^{eff}(M)$ + Finslerian corrections

$$ds^{2} = -A(r)dt^{2} + B(r)dr^{2} + r^{2}(d\theta^{2} + \sin^{2}\theta d\varphi^{2}).$$

$$A(R) = 1 + a_{1} \frac{GM}{c^{2}R} + a_{2} \left(\frac{GM}{c^{2}R}\right)^{2} + a_{3} \left(\frac{GM}{c^{2}R}\right)^{3} + \cdots;$$

$$B(R) = 1 + b_{1} \frac{GM}{c^{2}R} + b_{2} \left(\frac{GM}{c^{2}R}\right)^{2} + \cdots,$$

Dictionary:

$$I_a^{real} = I_a^{effective}$$

$$M = m_1 + m_2$$

$$\mu = m_1 m_2/M$$

$$\frac{\mathcal{E}_{\text{eff}}}{\mu c^2} = 1 + \frac{E_{\text{real}}^{\text{relative}}}{\mu c^2} \left(1 + \frac{\nu}{2} \frac{E_{\text{real}}^{\text{relative}}}{\mu c^2} \right)$$

$$\nu \equiv m_1 \, m_2 / M^2$$

Explicit form of the effective metric

The effective metric at 3PN + a 4PN correction

$$ds^2 = -A(r)dt^2 + B(r)dr^2 + r^2(d\theta^2 + \sin^2\theta d\varphi^2).$$

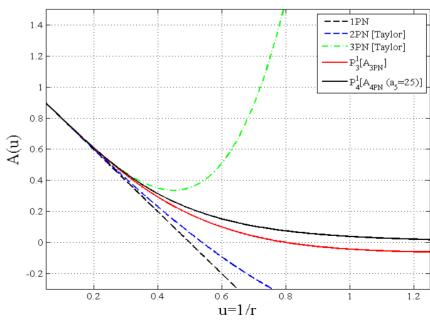

where the coefficients are a v-dependent "deformation" of the Schwarzschild ones:

$$(BA)^{3\text{PN}}(r) \equiv D^{3\text{PN}}(r) \equiv 1 - \frac{6\nu}{r^2} + 2(3\nu - 26)\frac{\nu}{r^3}.$$

$$A^{\text{Taylor}}(u) = 1 - 2u + 2\nu u^3 + \left(\frac{94}{3} - \frac{41}{32}\pi^2\right)\nu u^4 + a_5\nu u^5 \qquad u = 1/r$$

$$+ \mathcal{O}(\nu u^6),$$

- Extremely compact representation of PN dynamics
- Bad behaviour at 3PN. Padé resummation of A(r) is needed to ensure that an effective horizon exists.
- •Impose, by continuity with the Schwarzschild case, that A(r) has a simple zero at r~2.
- The a₅ constant parametrizes (yet) uncalculated 4PN corrections

The EOB Hamiltonian

The effective Hamiltonian (+quartic-in-momenta non-geodesic contribution at 3PN)

$$\hat{H}_{\text{eff}} \equiv \sqrt{p_{r_*}^2 + A\left(1 + \frac{p_{\varphi}^2}{r^2} + z_3 \frac{p_{r_*}^4}{r^2}\right)} \qquad \frac{ar_*}{dr} = \sqrt{\frac{B}{A}}$$

$$p_{r_*} = \left(\frac{A}{B}\right)^{1/2} p_r$$

The real EOB Hamiltonian of the binary system (from the energy map)

$$\hat{H}^{\text{EOB}} = \frac{1}{\nu} \sqrt{1 + 2\nu \left(\hat{H}_{\text{eff}} - 1\right)}$$

The Hamiltonian (and the related dynamics) depends, through the "potential" A(u), on the 4PN parameter a_5 . a_5 is a "free" parameter that needs to be fixed via comparisons with NR simulations.

$$M = m_1 + m_2$$

$$\nu = m_1 m_2 / (m_1 + m_2)^2$$

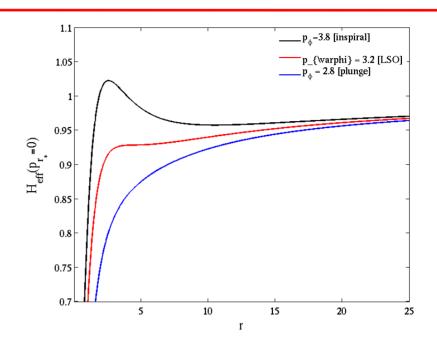

Hamilton's equation + radiation reaction

$$\frac{dr}{dt} = \left(\frac{A}{B}\right)^{1/2} \frac{\partial \hat{H}_{EOB}}{\partial p_{r_*}},$$

$$\frac{dp_{r_*}}{dt} = -\left(\frac{A}{B}\right)^{1/2} \frac{\partial \hat{H}_{EOB}}{\partial r},$$

$$\Omega \equiv \frac{d\varphi}{dt} = \frac{\partial \hat{H}_{EOB}}{\partial p_{\varphi}},$$

$$\frac{dp_{\varphi}}{dt} = \hat{\mathcal{F}}_{\varphi}.$$

Angular momentum loss due to GW emission: start from the PN expression for *radiation reaction* that is explicitly known during the quasi-circular adiabatic inspiral (3.5PN + 4PN correction)

$$\hat{\mathcal{F}}_{\varphi}^{\text{Taylor}} = -\frac{32}{5} \nu \,\Omega^5 \, r_{\omega}^4 \, \hat{F}^{\text{Taylor}}(v_{\varphi})$$

$$\hat{F}^{\text{Taylor}}(v) = 1 + A_2(\nu) \, v^2 + A_3(\nu) \, v^3 + A_4(\nu) \, v^4 + A_5(\nu) \, v^5 + A_6(\nu, \log v) \, v^6 + A_7(\nu) \, v^7 + A_8(\nu = 0, \log v) \, v^8$$

Needs resummation of energy flux!

The PN expansions are non-uniformly and non-monotonically convergent in the strong-field regime.

One needs to "resum" them in some form in order to extend their validity during the late-inspiral and plunge

- Factorize a simple pole in the GW energy flux
- Resum using near-diagonal Padé approximants (DIS98)

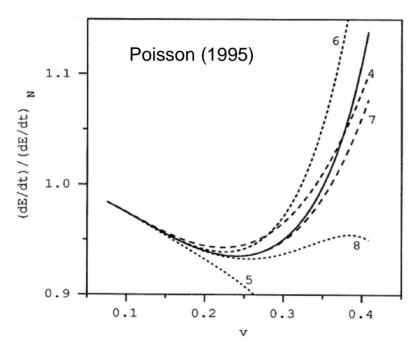

FIG. 1. Various representations of $(dE/dt)/(dE/dt)_N$ as a function of orbital velocity $v = (M/r)^{1/2} = (\pi M f)^{1/3}$. The solid curve represents the exact result P(v), as calculated numerically. The various broken curves represent the post-Newtonian approximations $P_n(v)$, for $n = \{4, 5, 6, 7, 8\}$. The smallest value of v corresponds to an orbital radius r of 175M; the largest value of v corresponds to r = 6M, the innermost stable circular orbit.

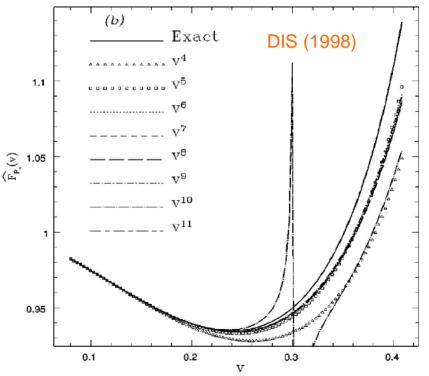

FIG. 3. Newton-normalized gravitational wave luminosity in the test particle limit: (a) *T*-approximants and (b) *P*-approximants.

Resumming radiation reaction

Padé resummation of
$$\hat{\mathcal{F}}_{\varphi}^{\mathrm{Taylor}} = -\frac{32}{5}\,\nu\,\Omega^5\,r_{\omega}^4\,\hat{F}^{\mathrm{Taylor}}(v_{\varphi})$$

- factorize a pole parametrized by v_{pole}
- consider logarithms as coefficients
- use comparable-mass 3.5PN+test-mass 4PN flux
- •choose P⁴₄ which has no spurious poles
- ■add non-quasi-circular correction parametrized by a^{RR} [with ε=0.12]
- •choose argument $v=r\Omega\psi^{1/3}$

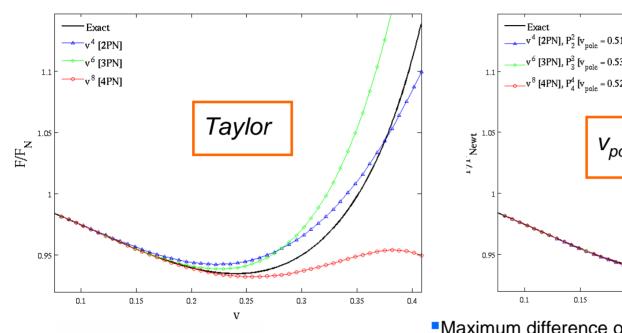

$$\hat{F}^{\text{resummed}}(v_{\varphi}) = \left(1 - \frac{v_{\varphi}}{v_{\text{pole}}}\right)^{-1} P_4^4 \left[\left(1 - \frac{v_{\varphi}}{v_{\text{pole}}}\right) \hat{F}^{\text{Taylor}}(v_{\varphi})\right] \left(1 + \bar{a}^{\text{RR}} \frac{p_{r_*}^2}{(r\Omega)^2 + \epsilon}\right)^{-1}$$

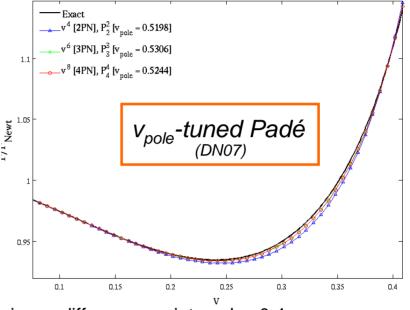

Note prefactor à la DG06

 $v_{\rm pole}$, $a^{\rm RR}$ are (in addition to a5 in $H_{\rm EOB}$) "free" parameters that need to be fixed via comparisons with NR simulations.

3.5PN + test-mass 4PN contribution

Comparing Taylor and (tuned) Padé in test-mass case

Maximum difference on interval v<0.4:</p>

Henri Padé, 1863-1953

Taylor(2PN): 0.039 Padé(2PN): 0.0069 Taylor(3PN): 0.130 Padé(3PN): 0.0033 Taylor(4PN): 0.189 Padé(4PN): 0.0035

Resummed EOB *metric* gravitational waveform: inspiral+plunge

- Zerilli-Moncrief normalized (even-parity) waveform (Real part gives h, & imaginary part gives h,).
- •Multipolar decomposition (expansion on spin-weighted spherical harmonics) here, l=m=2.

$$\left(\frac{c^2}{GM}\right)\Psi_{22}^{\text{insplunge}}(t) = -4\sqrt{\frac{\pi}{30}}\nu(r_{\omega}\Omega)^2 f_{22}^{\text{NQC}} F_{22} e^{-2i\Phi}$$

New PN-resummed (3+2PN) correction factor (DN07a, 07b): 3PN comparable mass + up to 5PN test-mass

$$F_{22}(t) = \hat{H}_{\text{eff}} T_{22} f_{22}(x(t)) e^{i\delta_{22}(t)}$$

• H_{eff}: resums an infinite number of binding energy contributions

$$T_{\ell m} = \frac{\Gamma(\ell + 1 - 2i\hat{k})}{\Gamma(\ell + 1)} e^{\pi\hat{k}} e^{2i\hat{k}\log(2kr_0)}$$

resums an infinite number of leading logarithms in tail effects (both amplitude and phase) obtained from exact solution of Coulomb wave problem

$$f_{22}(x; \nu) = P_2^3 \left[f_{22}^{\text{Taylor}}(x; \nu) \right]$$

Padé-resummed remaining PN-corrected amplitude [flexibility in choice of argument x(t)]

 δ_{22} : computed at 3.5PN

Non-quasi-circular corrections to waveform amplitude and phase:

$$f_{22}^{\text{NQC}} = \left[1 + a \frac{p_{r_*}^2}{(r\Omega)^2 + \epsilon}\right] \exp\left(+ib \frac{p_{r_*}}{r\Omega}\right)$$

EOB *metric* gravitational waveform: merger and ringdown

EOB approximate representation of the merger (DRT1972 inspired):

- sudden change of description around the "EOB light-ring" t=t_m (maximum of orbital frequency)
- "match" the insplunge waveform to a superposition of QNMs of the final Kerr black hole
- matching on a 5-teeth comb (found efficient in the test-mass limit, DN07a)
- comb of width 7M centered on the "EOB light-ring"
- •use 5 positive frequency QNMs (found to be near-optimal in the test-mass limit)
- •Final BH mass and angular momentum are computed from a fit to NR ringdown (5 eqs for 5 unknowns)

$$\Psi_{22}^{\text{ringdown}}(t) = \sum_{N} C_N^+ e^{-\sigma}$$

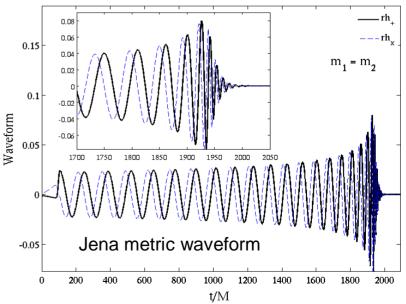

Total EOB waveform covering inspiral-merger and ringdown

$$h_{22}^{\text{EOB}}(t) = \theta(t_m - t) h_{22}^{\text{insplunge}}(t) + \theta(t - t_m) h_{22}^{\text{ringdown}}(t)$$

Accurate EOB-NR comparisons (and calibration)

NR, reduced eccentricity data used (non-spinning black holes only):

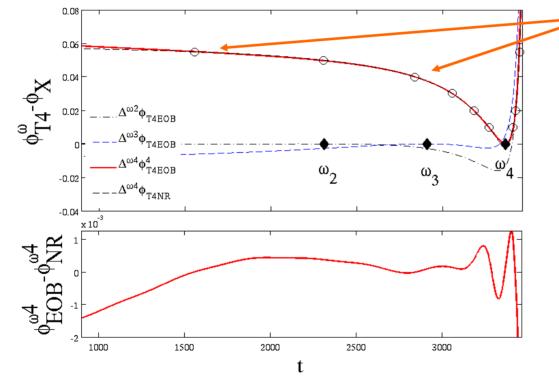

- •very accurate inspiral only data (m₁=m₂), 30 GW-cycles rψ₄ curvature waveform Caltech-Cornell [Boyle et al. 07] used up to GW frequency 0.1
- •Albert-Einstein-Institute, 12 GW-cycles metric (Zerilli) waveform, inspiral+merger data (m₁=m₂) [DNDPR,08]
- ■Jena, about 20 GW-cycles r_{ψ_4} curvature waveform, inspiral+merger data (m₁=m₂; m₁=2m₂; m₁=4m₂) [DNHHB,08]
- Getting the metric waveform by twice integrating the curvature waveform and subtracting linear floors.

Methodology for fitting EOB to NR data

Need to calibrate 3 EOB-flexibility parameters (a₅, v_{pole}, a_{RR})

•Use two phase differences [curvature waveforms] from published Caltech-Cornell data to have two equations to determine vpole(a₅) and a_{RR}(a₅)

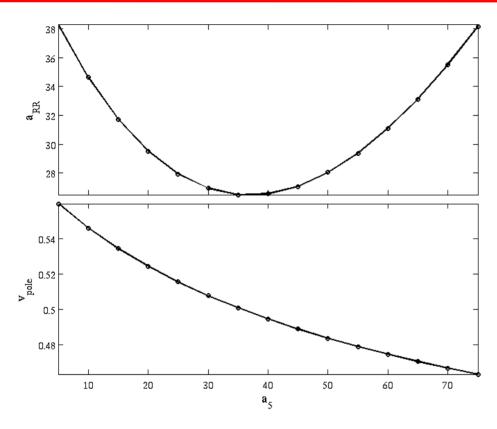

Impose that the phase Differences T4-EOB and T4-CC agree at these two points

Residual phase difference EOB-NR [curvature waveforms]

[■]Then constrain a₅ by comparing the phases of EOB and Jena (+AEI) data.

Correlating EOB flexibility parameters

■Use the CC data to express the two free parameters as functions of a₅.

Done here with points measured from a published figure. Checked to be consistent with actual Caltech-Cornell NR data (courtesy of Boyle et al.)

TABLE II: Explicit values of the EOB effective parameters $\bar{a}_{\rm RR}$ and $v_{\rm pole}$ for a certain sample of a_5 . These values correspond to imposing the two constraints $\rho_{\omega_4}^{\delta t'_{\omega_4}} \simeq 1 \pm 10^{-4} \simeq \rho_{\omega_4}^{\delta t_{\omega_4}}$.

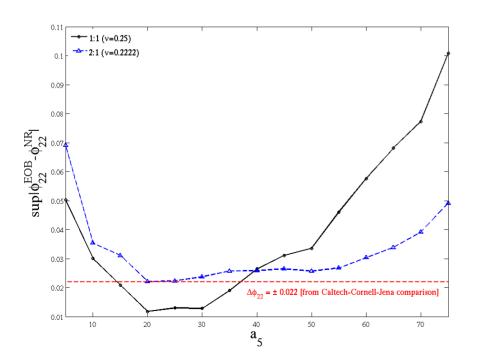

a_5	$ar{a}_{ ext{RR}}$	$v_{ m pole}$

Use late-plunge Jena data to constrain the a₅ parameter

Use "plunge and merger" data that are more sensitive to the effect of a₅

Accurate simulations from Jena group for several mass ratios. For 1:1, D=12 and 20 GW-cycles waveform. [Double time-integration to get metric waveform]

Diagnostics: L_{∞} norm of the [metric waveform] phase difference in the late plunge: from -10.5 to -1.2 GW-cycles before merger, i.e., frequency 0.2 0.059< ω <0.19)

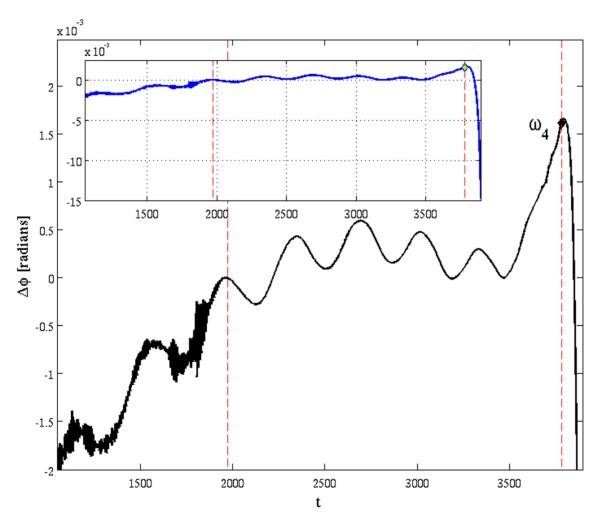

- Presence of a clear minimum (0.01) for the 1:1 mass ratio case
- Consistency with 2:1 mass ratio (where the minimum is more shallow)

current best-bet value: $a_5 \sim 25$

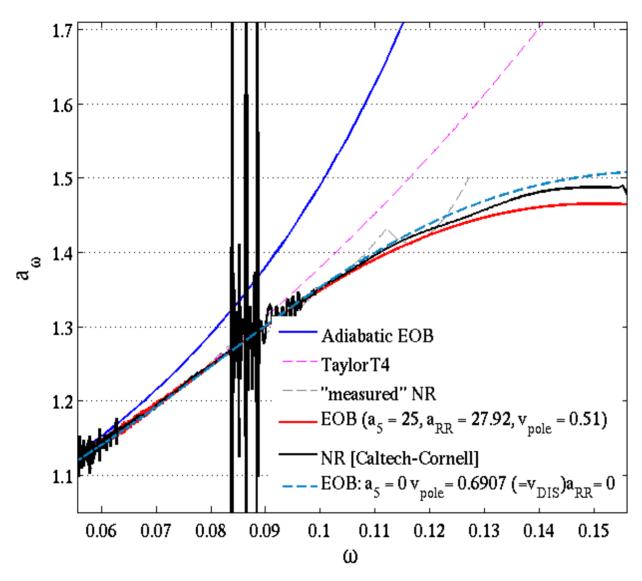

Range of allowed values of a₅ depending on error level in NR data (? 14<a₅<37 ?)

Curvature-waveform phase difference EOB-CC (actual data) for $a_5=25$

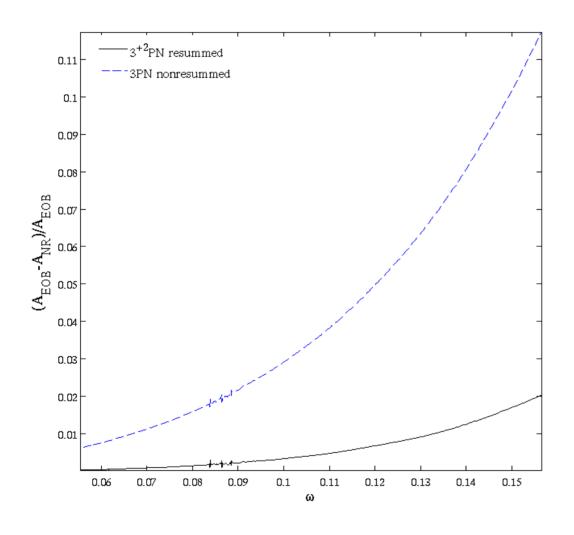

- Close up (black): maximum phase difference 0.002 radians up to GW frequency 0.1 (OK with DN07b, which used published data)
- ■Full range (blue, inset): maximum phase difference 0.015 radians accumulated between frequency 0.1 and 0.156
- Two "pinching-times" indicated

Comparing *curvature* phase acceleration curves: CC (actual data), TaylorT4, adiabatic, untuned and tuned EOB

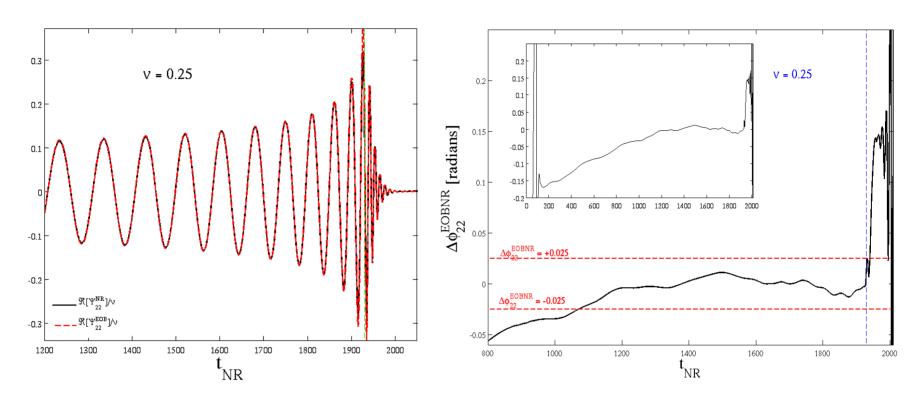

- Most "intrinsic" curve (OK with DN07b, which used published data)
- Evident presence of nonadiabatic effects [DN07b]
- T4: strongly deviates from NR after GW frequency 0.1

(Fractional) curvature amplitude difference EOB-CC (actual data) for $a_5=25$

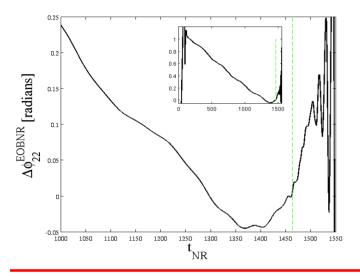

- ■Nonresummed: fractional differences start at the 1% level and build up to more than 10%
- New resummed EOB amplitude: fractional differences start at the 0.04% level and build up to only 2%
- Resummation: factor ~20 improvement!

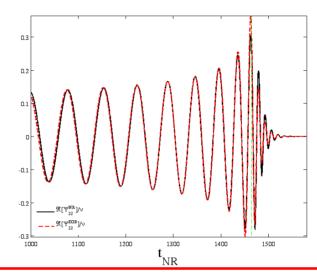

Comparing EOB-NR *metric* waveforms 1:1 case: Jena data

- Metric waveforms from double time-integration of NR curvature waveforms
- -0.025<Δφ₂₂<+0.025 radians (=0.004 GW cycles) over 730 M [1200M-1930M]
- At merger, phase jump of only 0.15 radians [=0.02 GW cycles].
- •We use the same values of flexibility parameters for CC and Jena data: consistency achieved!

Comparing EOB-NR *metric* waveforms 4:1 case: Jena data

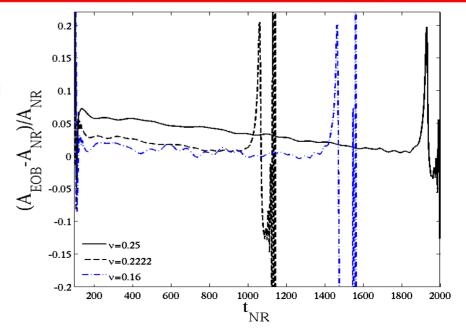

4:1 mass ratio

- Larger accumulated dephasing
- The accuracy of the simulation can be further improved (truncation error is still dominant during the early-inspiral phase)

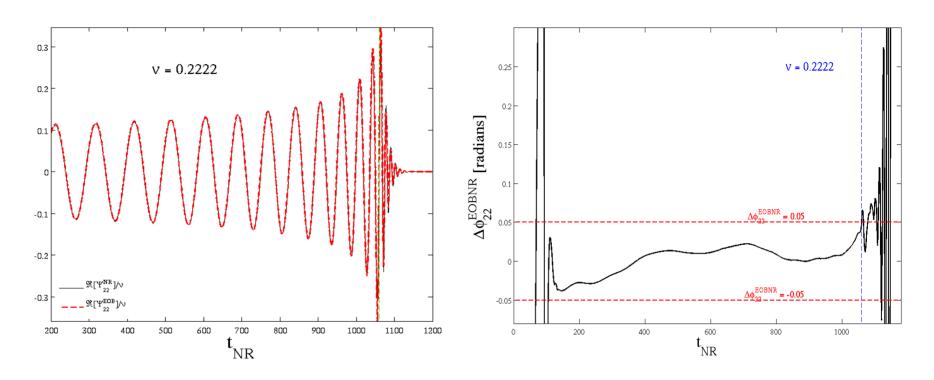

Comparing EOB-NR *metric* amplitudes: Jena data

Good agreement between the amplitudes:

- Best fractional agreement [equal-mass]: 0.005 during late inspiral
- •The NR waves are extracted at finite radius (r=90M)
- The agreement improves for smaller v
- Maximum difference of 20% due to the rather coarse (but still accurate in phasing) matching procedure.

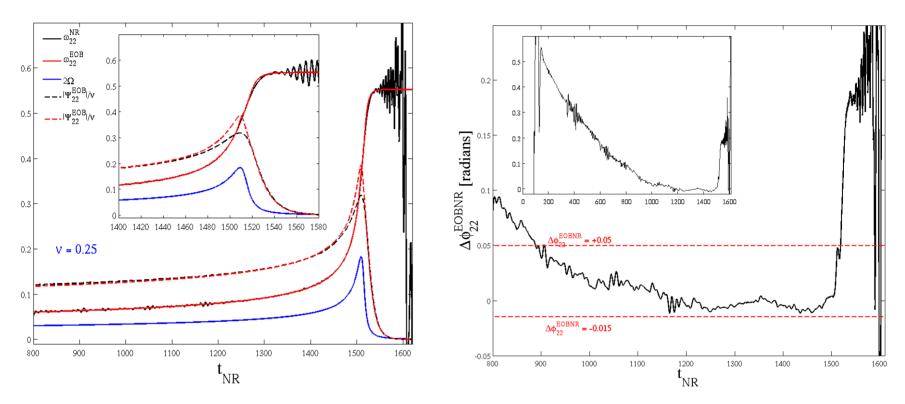

Comparing EOB-NR *metric* waveforms 2:1 case: Jena data

- Metric waveforms from double time-integration of NR curvature waveforms
- $-0.05 < \Delta \phi_{22} < +0.05$ radians (=0.008 GW cycles) over 957M [143M-1100M]
- At merger, phase jump of only 0.06 radians [= 0.009 GW cycles].
- •We use the same values of flexibility parameters for CC and Jena data: consistency achieved!

Consistency with AEI metric waveform 1:1 data

- NR metric waveforms [no need of double time-integration from curvature waveforms]
- $^{-0.015}$ < $\Delta \phi_{22}$ <0.05 radians (=0.008 GW cycles) over 600M [900M-1500M]
- At merger, phase jumps by 0.18 radians [= 0.028 GW cycles].
- •We use the same values of flexibility parameters for CC and AEI data: consistency achieved!

Conclusions

- The EOB formalism made several (qualitative and semi-quantitative) predictions that have been broadly confirmed by NR
- The natural *flexibility* of the EOB parameters leads to a constructive *synergy with NR* results
- The EOB formalism can provide high-accuracy *parameter free* templates $h(m_1, m_2)$ for GWs from BBH coalescence, with unprecedented agreement with NR data, and for any mass ratio.
- Even without using the full flexibility, and without using the resummed 3PN waveform, EOB provides *faithful* templates [Buonanno et al. 2007]
- It is predictive and can give us a physical understanding of dynamics and radiation: energy loss, final spin, recoil,...
- EOB dynamics can help to reduce eccentricity in numerical simulations (as originally suggested BD99,00)
