Problem and Objective

General Physical Problem: EMRIs

- Modelling of the dynamics and Gravitational Wave emission of an Extreme Mass Ratio Inspiral.

General Methodology: self-force

- Perturbative approach around a stationary black hole: calculation of the gravitational *self-force*.
- **Time-domain approach** to the resolution of the self-force with **singular sources** (*a posteriori mode-sum* regularization of the solution).
- Use of **trivial Initial Data**.

Specific objective: Jost solutions [JLJ, C. Sopena & P. Canizares, PRD 83, 061503(R) (2011)]

Understanding/clarifying the possible emergence of persistent spurious solutions in time-domain schemes, referred to as a *Jost junk solution*, that may contaminate self-force calculations. **Are Time Domain calculations safe?**

- 6 Conclusions

Time domain approach: singular sources and trivial data

Evolution equation

Let us assume a spherically symmetric Black Hole.

Field $\Psi(t, r)$, spherical harmonic component of retarded field (most gauges):

$$[-\partial_t^2 + \partial_{r^*}^2 - V(r)] \Psi(t, r) = f(r) [G(t, r) \delta(r - r_p(t)) + F(t, r) \delta'(r - r_p(t))]$$

Trivial Initial data

Correct physical initial data not known. Common practice:

$$\Psi|_{t=t_o} = (\partial_t \Psi)|_{t=t_o} = 0$$

Claim: [Field, Hesthaven & Lau, PRD 81, 124030 (2010)]

Jost solutions may appear as a consequence of **inconsistent singular sources** and **trivial initial data**.

Time domain approach: singular sources and trivial data

Evolution equation

Let us assume a spherically symmetric Black Hole.

Field $\Psi(t, r)$, spherical harmonic component of retarded field (most gauges):

$$[-\partial_t^2 + \partial_{r^*}^2 - V(r)] \Psi(t, r) = f(r) [G(t, r) \delta(r - r_p(t)) + F(t, r) \delta'(r - r_p(t))]$$

Trivial Initial data

Correct physical initial data not known. Common practice:

$$\Psi|_{t=t_o} = (\partial_t \Psi)|_{t=t_o} = 0$$

Claim: [Field, Hesthaven & Lau, PRD 81, 124030 (2010)]

Jost solutions may appear as a consequence of **inconsistent singular sources** and **trivial initial data**.

Jost solution: numerical approach I

Impulsive solution: construction

$\Psi_{\text{Impulsive}}$: use sources $F(t, r)$, $G(t, r)$ and trivial data.

Smoothed ('consistent') solution: construction

Define smoothed sources (consistent with trivial data):

$$F_{\tau}^s(t, r) \equiv \alpha(t, \tau)F(t, r) \text{ and } G_{\tau}^s(t, r) \equiv \alpha(t, \tau)G(t, r)$$

with $\alpha(t_0, \tau) = 0$ and $\alpha(t, \tau) = 1$, for $t \gg \tau$.

Ψ_{Smooth} : use sources $F_{\tau}^s(t, r)$, $G_{\tau}^s(t, r)$ and trivial data.

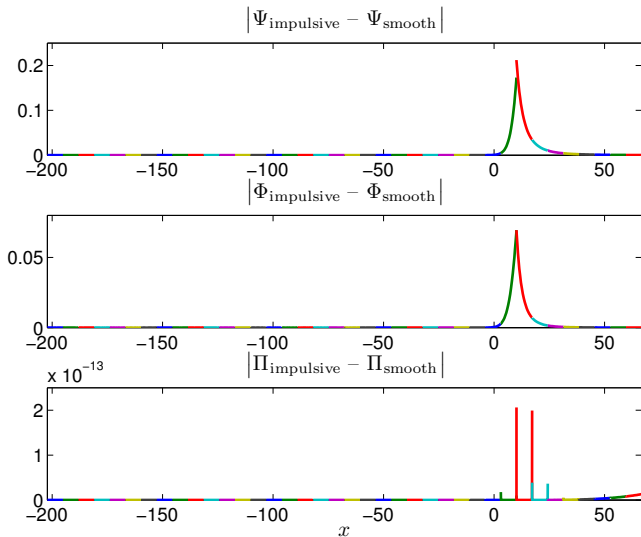

Numerical Jost solution: construction

$$\Psi_{\text{Jost}}^N \equiv \Psi_{\text{Impulsive}} - \Psi_{\text{Smooth}}$$

Properties:

- (i) It is time independent: $\partial_t \Psi_{\text{Jost}}^N = 0, \forall t$.
- (ii) It has a jump at the particle: $[\Psi_{\text{Jost}}^N]_p = -f_p^{-1}F(t_0, r_p)$, where $f_p \equiv f(r_p)$.
- (iii) The spatial derivative, $\partial_{r^*} \Psi_{\text{Jost}}^N$, is continuous at $r = r_p$.

Jost solution: numerical approach II

[Field, Hesthaven & Lau, PRD 81, 124030 (2010)]

Jost solution: numerical approach II

[Field, Hesthaven & Lau, PRD 81, 124030 (2010)]

Jost solution: analytical approach

Analytical Jost solution

Motivated by the numerical solution, construct:

$$\Psi_{\text{Jost}}^{\text{A}} \equiv \Psi_{\text{Jost}}^{\text{A},-} \Theta_- + \Psi_{\text{Jost}}^{\text{A},+} \Theta_+$$

with: $\Theta_+ \equiv \Theta(r^* - r_p^*)$, $\Theta_- \equiv \Theta(r_p^* - r^*)$.
 (Θ the Heaviside step function)

Stationary multi-domain equation

$\Psi_{\text{Jost}}^{\text{A},-}$ and $\Psi_{\text{Jost}}^{\text{A},+}$ satisfy

$$[\partial_{r^*}^2 - V(r)] \Psi_{\text{Jost}}^{\text{A},\pm} = 0$$

with $[\Psi_{\text{Jost}}^{\text{A}}]_p = -f_p^{-1} F(t_o, r_p)$. This means $\Psi_{\text{Jost}}^{\text{A}}$ satisfy:

$$[\partial_{r^*}^2 - V(r)] \Psi_{\text{Jost}}^{\text{A}} = -f_p F(t_o, r_p) \delta'(r - r_p),$$

Equivalence Numerical and Analytical approach

Differences between $\Psi_{\text{Jost}}^{\text{A}}$ and $\Psi_{\text{Jost}}^{\text{N}}$ vanish to numerical precision.

Posed questions

The Jost solution Problem:

There exists a Difference between the smoothed (consistent) and the impulsive (inconsistent) solutions:

(numerical) *Artifact* or *Real*?

An early *warning*...

Sources are identical at late times \implies Difference of solutions should be a solution of the homogeneous..

But the Jost solution has a delta source...

Are we actually solving *different* problems?

From delta source to jumps I: idea

Particle-Without-Particle approach [Canizares & Sopena, PRD79, 084020 (2009)]

Basic idea to deal with the *two-scales problem* in EMRIs:

Transform:

- The problem with a **singular (delta) sources**.

Into:

- **Jump conditions** between two homogeneous wave-equations in neighbouring domains, by placing the particle at the boundary between two domains.

From delta source to jumps II: first-order and multidomain system

Evolution system: Second-order formulation

$$[-\partial_t^2 + \partial_{r^*}^2 - V(r)] \Psi(t, r) = \underbrace{f(r) [G(t, r) \delta(r - r_p(t)) + F(t, r) \delta'(r - r_p(t))]}_{S(t, r)}$$

From delta source to jumps II: first-order and multidomain system

Evolution system: First-order formulation

Introduce fields: $\phi \equiv \partial_t \Psi$, $\varphi \equiv \partial_{r^*} \Psi$

$$\partial_t \Psi = \phi,$$

Evolution equations: $\partial_t \phi = \partial_{r^*} \varphi - V(r) \Psi - S(t, r)$

$$\partial_t \varphi = \partial_{r^*} \phi$$

Multidomain approach

Ansatz for field splitting (only two domains, circular orbit, just for simplicity!):

$$\Psi = \Psi^- \Theta_- + \Psi^+ \Theta_+$$

$$\phi = \phi^- \Theta_- + \phi^+ \Theta_+$$

$$\varphi = \varphi^- \Theta_- + \varphi^+ \Theta_+ + [\Psi]_p \delta(r^* - r_p^*)$$

with a jump for a field χ : $[\chi]_p \equiv \lim_{\epsilon \rightarrow 0} (\chi(r_p + \epsilon) - \chi(r_p - \epsilon))$

From delta source to jumps III: the system with jumps

Evolution system

Homogeneous evolution equations AND **jump conditions**:

$$\begin{aligned}
 \partial_t \Psi^\pm &= \phi^\pm & [\Psi]_p(t) &= f_p^{-1} F(t, r_p) \\
 \partial_t \phi^\pm &= \partial_{r^*} \phi^\pm - V(r) \Psi^\pm & [\phi]_p(t) &= f_p^{-1} (\partial_t F)(t, r_p) \\
 \partial_t \varphi^\pm &= \partial_{r^*} \phi^\pm & [\varphi]_p(t) &= G(t, r_p) - f_p^{-1} (\partial_{r^*} F)(t, r_p)
 \end{aligned}$$

Remarks:

- Not all initial conditions are consistent with singular sources.
- Jumps $[\Psi]_p$ and $[\phi]_p$ contain redundant information: one is the derivative of the other.
BUT if $[\Psi]_p(t_o) = f_p^{-1} F(t_o, r_p)$ is not enforced, equivalence to original system is lost.

Outline

- 1 Problem and Objective
- 2 Review of the Jost solutions issue
- 3 Casting *singular sources* as *jump* conditions
 - On the equivalence of the resulting PDE systems
 - Illustration in the charged scalar particle
- 4 A perspective from late times
- 5 A by-product: smooth *time switch-on* of the sources
- 6 Conclusions

Evolution system with jumps integrated: first version

Reinserting the sources in the system [Field, Hesthaven & Lau, PRD 81, 124030 (2010)]

$$\begin{aligned}\partial_t \Psi &= \varphi \\ \partial_t \phi &= \partial_{r^*} \varphi - V(r) \Psi - J_\varphi \delta(r^* - r_p^*), \\ \partial_t \varphi &= \partial_{r^*} \phi + J_\phi \delta(r^* - r_p^*)\end{aligned}$$

with $J_\varphi = [\varphi]_p$, $J_\phi = [\phi]_p$

Remarks:

- $[\Psi]_p(t)$ is not explicitly enforced.
- It is only enforced through $[\varphi]_p$: i.e. only $\partial_t [\Psi]_p(t)$ is enforced.
- $[\Psi]_p(t_o) = f_p^{-1} F(t_o, r_p)$ is never enforced.
- The resulting system is inequivalent to the original one.
- *Jost solutions* appear in this system.
- But note that $[\Psi]_p(t_o) = 0$ is consistent with the trivial initial data. A **choice** is necessary: either Initial Data or the Sources...

Evolution system with jumps integrated: second version

Remarks:

Redefine: $\tilde{\varphi} = \varphi + [\Psi]_p \delta(r^* - r_p^*)$ The system is then:

$$\begin{aligned}\partial_t \phi &= \partial_{r^*} \tilde{\varphi} - V(r) \Psi - J_\varphi \delta(r^* - r_p^*) - J_\Psi \delta'(r^* - r_p^*) \\ \partial_t \tilde{\varphi} &= \partial_{r^*} \phi,\end{aligned}$$

with $J_\varphi = [\varphi]_p$, $J_\Psi = [\Psi]_p$.

Remarks:

- $[\Psi]_p(t)$ **IS** explicitly enforced.
- The system **IS** equivalent to the original one.
- No Jost solutions appear in this system.

Main observation

Jost junk solutions appear when implementing a *finite* jump condition, $[\Psi]_p$, through an infinitesimal equation ($\partial_t [\Psi]_p = [\phi]_p$) *without* simultaneously imposing the initial value $[\Psi]_p(t_0)$ consistent with the singular source.

Charged particle in a circular orbit around Schwarzschild

Evolution system

Spherical harmonic modes: $\Phi_{\ell m}$, satisfy our model equation with: $\Psi = r\Phi_{\ell m}$, $F = 0$, and $G = f^{-1}S_{\ell m}$.

Characteristic variables (Ψ, u, v) : $(u, v) = (\phi - \varphi, \phi + \varphi)$.

$$\begin{aligned} \partial_t \Psi^\pm &= (u^\pm + v^\pm)/2, & [\Psi]_p(t) &= 0 \\ \partial_t u^\pm &= -\partial_{r^*} u^\pm - V(r)\Psi^\pm, & [u]_p(t) &= -G(t, r_p) \\ \partial_t v^\pm &= \partial_{r^*} v^\pm - V(r)\Psi^\pm, & [v]_p(t) &= G(t, r_p) \end{aligned}$$

Enforcing jump conditions [C. Sopena, P. Canizares & JLJ, PRD 82, 044023 (2010)]

Two different strategies:

- i) **Approach I:** Finite jumps $[u]_p(t)$ and $[v]_p(t)$ directly enforced with triv. ID.
- ii) **Approach II:** Jump time derivatives, $d[u]_p/dt$ and $d[v]_p/dt$, enforced as extra evolution equations with appropriately modified (non-trivial) ID *guaranteeing correct initial values of the jumps*: $[u]_p(t_o)$ and $[v]_p(t_o)$.

- ii) **Approach II:** Jump time derivatives, $d[u]_p/dt$ and $d[v]_p/dt$, enforced as extra evolution equations with appropriately modified (non-trivial) ID *guaranteeing correct initial values of the jumps:* $[u]_p(t_o)$ and $[v]_p(t_o)$.

Generating a *Jost* solution

Testing our understanding of the *Jost* problem

If our understanding of the problem is correct, a *Jost-like* solution should emerge when calculating the **difference** between the solutions in **Approches I and II**, but using trivial ID in **both** cases.

Generating a *Jost* solution

Testing our understanding of the *Jost* problem

If our understanding of the problem is correct, a *Jost-like* solution should emerge when calculating the **difference** between the solutions in **Approches I and II**, but using trivial ID in **both** cases.

Outline

- 1 Problem and Objective
- 2 Review of the Jost solutions issue
- 3 Casting *singular sources* as *jump* conditions
 - On the equivalence of the resulting PDE systems
 - Illustration in the charged scalar particle
- 4 A perspective from late times
- 5 A by-product: smooth *time switch-on* of the sources
- 6 Conclusions

Perspective from late times I

Hitherto, focus on *initial data*. But...

Crucial point: sources faithfully implemented at late times

- Late times: in the studied problem, the only relevant element in late times analysis is the correct implementation of the sources.
- Choice of initial data should not play any role: any intermediate-time data can be taken as valid ID.

But then, why do the *smooth time switch-on* solutions work...?

The role of the smooth time switch-on $\alpha(t, \tau)$

It **guarantees the correct implementation of the late time sources** *when the source is implemented through an evolution equation for the jumps, with zero initial values.*

Perspective from late times II

Sources implemented through *smoothed jumps* with trivial ID

- Consider a field χ with jump condition and smoothed jump condition

$$[\chi]_p = J_\chi(t), \quad [\tilde{\chi}]_p = \alpha(t, \tau) J_\chi(t)$$

- Implement the jumps using evolution equations:

$$d[\chi]_p/dt = J'_\chi, \quad d[\tilde{\chi}]_p/dt = (\alpha J_\chi)'$$

with zero initial values: $[\chi]_p(t_o) = [\tilde{\chi}]_p(t_o) = 0$,

- Then

$$\begin{aligned} [\chi]_p &= J_\chi(t) - J_\chi(t_o), \\ [\tilde{\chi}]_p &= \alpha(t, \tau) J_\chi(t) - \alpha(t_o, \tau) J_\chi(t_o) \\ &= \alpha(t, \tau) J_\chi(t) \simeq J_\chi(t) \text{ (for } t \gg \tau) \end{aligned}$$

Conclusion

Smooth solution Ψ_{Smooth} solves the correct dynamical equation, whereas the Impulsive solution $\Psi_{\text{Impulsive}}$ does not (it is *contaminated by a Jost solution*).

The smooth switch-on as a high-frequency noise filter

We have learned:

The *smooth switch-on* is not the critical element in the discussion of the Jost solution: it is a *sufficient* prescription guaranteeing consistency in a particular approach.

But it certainly improves the consistency between the source and the ID...

By-products of using $\alpha(t, \tau)$ [Field, Hesthaven & Lau, *Class. Quantum Grav.* 26, 165010 (2009)]

- Reduces the burst of junk radiation [Field, Hesthaven & Lau, *CQG* 26, 165010 (2009)].
- More importantly: it can be critical in the calculation of the self-force in certain approaches. In the **Approach I** [C. Sopena, P. Canizares & JLJ, *PRD* 82, 044023 (2010), JLJ, C. Sopena & P. Canizares, *PRD* 83, 061503(R) (2011)]:
 - High-frequency numerical noise due to instantaneous switch-on of the source. Very slow time decay (much larger than the orbital time scale).
 - Noise can be eliminated by: a) increasing the resolution, or b) using a numerical filter (**remark**: this provides an explicit example of correct solution with both singular sources AND trivial data).
 - The use of the *smooth switch-on* of the source provides a natural filter.

Calculation of self-force in **Approach I** to the jumps

Components of the self-force, $(\Phi_t, \Phi_r, \Phi_\phi)$, with (“On”) and without (“Off”) time smooth switch-on: No recovery of the second significant digit in $\Phi_r = 1.677 \cdot 10^{-4}$, $\Phi_t = 3.609 \cdot 10^{-4}$ in the “Off” case.

$(r_p = 6M, t_{\text{fin}} = 250M > 2 \cdot T_{\text{orb}} = 2 \cdot 2\pi(r_p^3/M)^{\frac{1}{2}} \approx 184.69M)$

Calculation of self-force in **Approach I** to the jumps

Components of the self-force, $(\Phi_t, \Phi_r, \Phi_\phi)$, with (“On”) and without (“Off”) time smooth switch-on: No recovery of the second significant digit in $\Phi_r = 1.677 \cdot 10^{-4}$, $\Phi_t = 3.609 \cdot 10^{-4}$ in the “Off” case.

$$(r_p = 6M, t_{\text{fin}} = 250M > 2 \cdot T_{\text{orb}} = 2 \cdot 2\pi(r_p^3/M)^{\frac{1}{2}} \approx 184.69M)$$

- 6 Conclusions

Conclusions

Conclusions

- **No contamination of the retarded solution by Jost junk solutions, as long as the sources are faithfully implemented at late times.**
- It is NOT a numerical issue.
- The conclusion above is conceptually independent of the Initial Data and/or the use of a *smooth time switch-on*.
- The use of a *smooth time switch-on* of the sources prevents the high-frequency noise that spoils self-force calculations in some numerical schemes.
- Possible extension of this last point to other scenarios (e.g. junk radiation in numerical relativity initial data...)?
