THE ASTROPHYSICS OF EMRIS

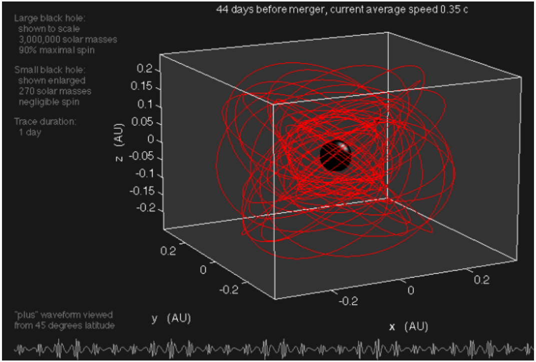
Capture of compact objects by SMBHs

Pau Amaro Seoane

June 29, 2015

Max-Planck Institute for Gravitational Physics (Albert Einstein Institute)

CAPTURE OF COMPACT OBJECTS



[Figure Steve Drasco]

- Stellar mass object spiraling into $10^4 - 10^6\, M_\bullet$
- This range of masses corresponds to relaxed nuclei (!)
- Only compact objects (extended stars disrupted early)
- With eLISA stellar BH $z \gtrsim 0.7$

WHY ARE EMRIS INTERESTING?

- SMBH binaries the “holy grial” but: There has not been any other mission conceived, planned or even thought of ever that can do the science that we can do with EMRIs

WHY ARE EMRIS INTERESTING?

- SMBH binaries the “holy grial” but: There has not been any other mission conceived, planned or even thought of ever that can do the science that we can do with EMRIs
- GR is a theory, needs corroboration: EMRIs unique probe in the strong regime

WHY ARE EMRIS INTERESTING?

- SMBH binaries the "holy grial" but: There has not been any other mission conceived, planned or even thought of ever that can do the science that we can do with EMRIs
- GR is a theory, needs corroboration: EMRIs unique probe in the strong regime
- Tests of alternative theories (e.g. Chern-Simons gravity): EMRIs will allow "geo"desic mapping of space-time

WHY ARE EMRIS INTERESTING?

- SMBH binaries the “holy grial” but: There has not been any other mission conceived, planned or even thought of ever that can do the science that we can do with EMRIs
- GR is a theory, needs corroboration: EMRIs unique probe in the strong regime
- Tests of alternative theories (e.g. Chern-Simons gravity): EMRIs will allow “geo”desic mapping of space-time
- Measures mass and spin with unprecedent precision

WHY ARE EMRIS INTERESTING?

- SMBH binaries the “holy grial” but: There has not been any other mission conceived, planned or even thought of ever that can do the science that we can do with EMRIs
- GR is a theory, needs corroboration: EMRIs unique probe in the strong regime
- Tests of alternative theories (e.g. Chern-Simons gravity): EMRIs will allow “geo”desic mapping of space-time
- Measures mass and spin with unprecedent precision
- Bridge between astrophysics and GR

WHY ARE EMRIS DIFFICULT?

- This is not “just” the two-body problem in GR: This is the 2-b in GR + the 10^6-body problem in Newtonian physics

- This is not “just” the two-body problem in GR: This is the 2-b in GR + the 10^6-body problem in Newtonian physics
- I.e.: You have to understand astrophysics and GR

WHY ARE EMRIS DIFFICULT?

- This is not "just" the two-body problem in GR: This is the 2-b in GR + the 10^6-body problem in Newtonian physics
- I.e.: You have to understand astrophysics and GR
- Very difficult problem to solve: Important science comes at a price

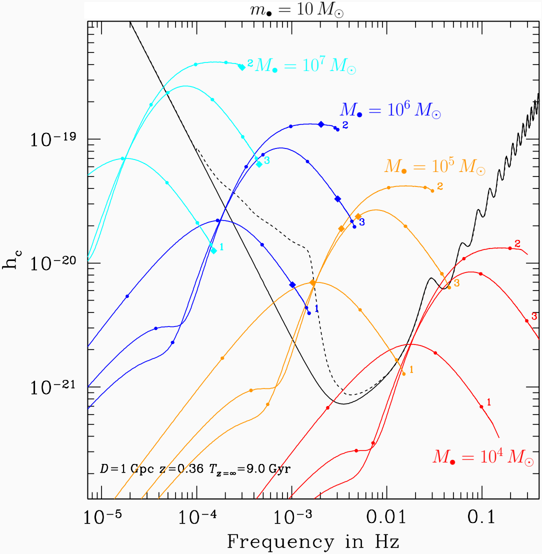
WHY ARE EMRIS DIFFICULT?

- This is not "just" the two-body problem in GR: This is the 2-b in GR + the 10^6-body problem in Newtonian physics
- I.e.: You have to understand astrophysics and GR
- Very difficult problem to solve: Important science comes at a price
- Many years before launch we're making new discoveries

WHY ARE EMRIS DIFFICULT?

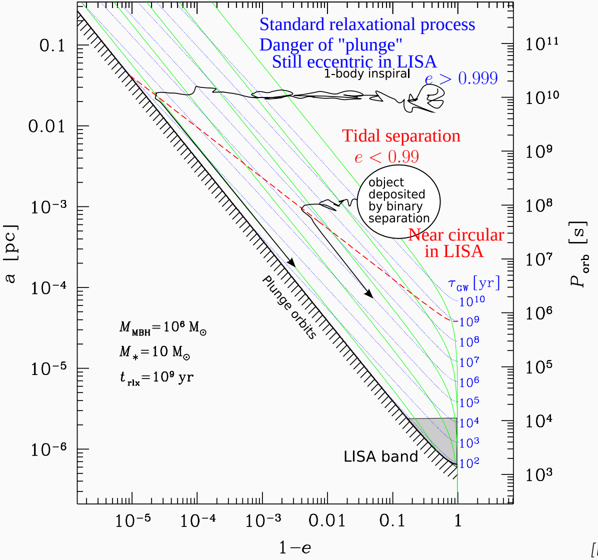
- This is not "just" the two-body problem in GR: This is the 2-b in GR + the 10^6-body problem in Newtonian physics
- I.e.: You have to understand astrophysics and GR
- Very difficult problem to solve: Important science comes at a price
- Many years before launch we're making new discoveries
- In this talk we'll see some of these difficulties, and how we've made progress: Microphysics around SMBHs

RANGE OF MASSES



[PAS, LRR 2015]

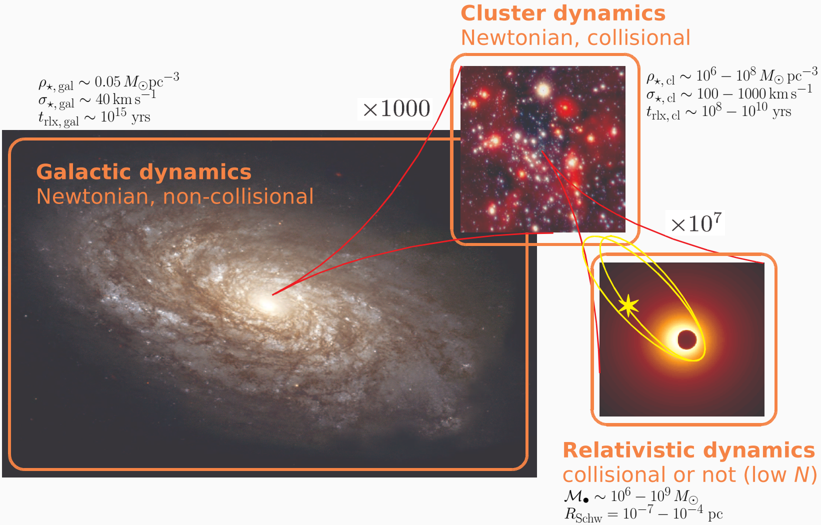
DICHOTOMIZING AN EMRI



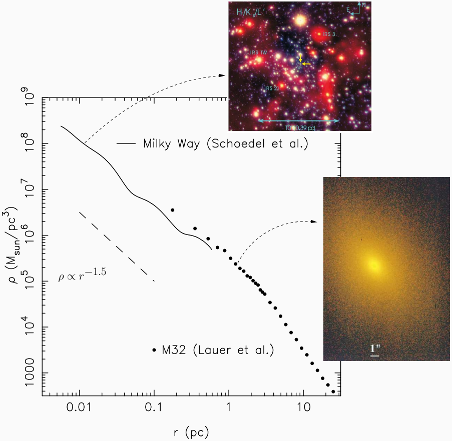
[PAS, LRR 2015]

DISTRIBUTION OF STARS AROUND SMBHS

THE THREE REALMS OF STELLAR DYNAMICS

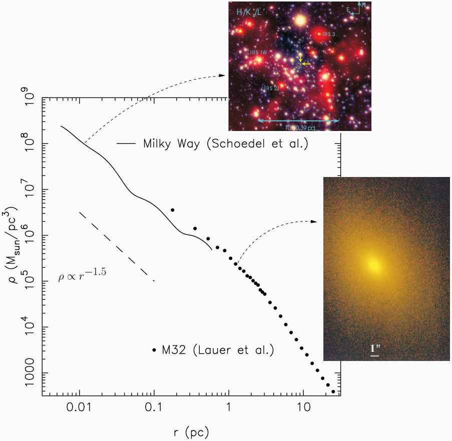


[PAS, LRR 2015]



[Adapted from Merritt 2006]

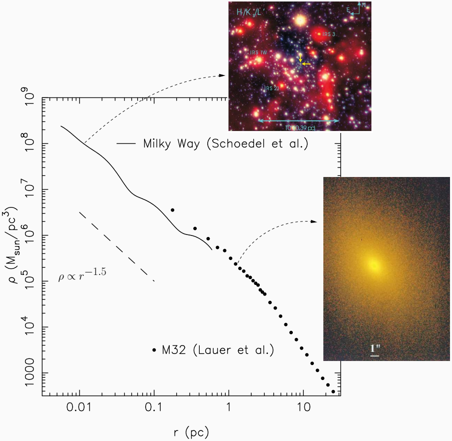
- 0th question: How many stars? How do they distribute?



[Adapted from Merritt 2006]

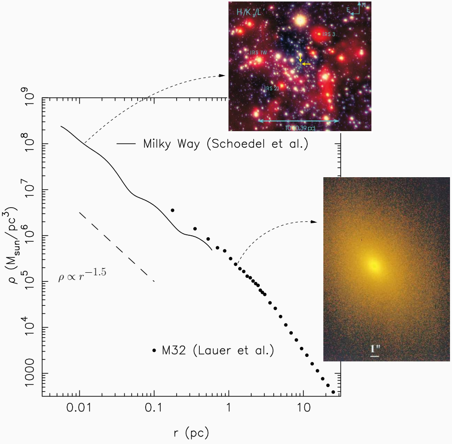
- 0th question: How many stars? How do they distribute?
- Very few observations R_h difficult to resolve

HOW MANY A YEAR?



[Adapted from Merritt 2006]

- 0th question: How many stars? How do they distribute?
- Very few observations R_h difficult to resolve
- To study inner region have to assume underlying population, deproject observation, assume observed star is tracing invisible population



[Adapted from Merritt 2006]

- ▷ 0th question: How many stars? How do they distribute?
- ▷ Very few observations R_h difficult to resolve
- ▷ To study inner region have to assume underlying population, deproject observation, assume observed star is tracing invisible population
  - Considerable amount of modelling: Are these profiles a coincidence?

MASS SEGREGATION

- Classical problem in stellar dynamics: Statistical thermal equilibrium $f(E) \propto e^{-E/\sigma^2}$ must be violated close to the MBH ($R_{\rm t}$, $R_{\rm Schw}$, $R_{\rm coll}$)

- Classical problem in stellar dynamics: Statistical thermal equilibrium $f(E) \propto e^{-E/\sigma^2}$ must be violated close to the MBH (R_{t}, R_{Schw}, R_{coll})
- There exists a Steady state with net inward flux of stars and energy

  [Peebles 1972]

MASS SEGREGATION

- Classical problem in stellar dynamics: Statistical thermal equilibrium $f(E) \propto e^{-E/\sigma^2}$ must be violated close to the MBH (R_{t}, R_{Schw}, R_{coll})
- There exists a Steady state with net inward flux of stars and energy

  [Peebles 1972]
- If single-mass: quasi-steady solution takes power-law form (isotropic DF) $f(E) \sim E^p$, $\rho(r) \sim r^{-\gamma}$, with $\gamma = 3/2 + p$

- Classical problem in stellar dynamics: Statistical thermal equilibrium $f(E) \propto e^{-E/\sigma^2}$ must be violated close to the MBH ($R_{\rm t}$, $R_{\rm Schw}$, $R_{\rm coll}$)
- There exists a Steady state with net inward flux of stars and energy *[Peebles 1972]*
- If single-mass: quasi-steady solution takes power-law form (isotropic DF) $f(E) \sim E^p$, $\rho(r) \sim r^{-\gamma}$, with $\gamma = 3/2 + p$
- Confirmed later with a detailed kinematic treatment for single-mass *[Bahcall & Wolf 1976]*: $\gamma = 7/4$ and $p = \gamma - 3/2 = 1/4$

- "Only a fool tries to solve a complicated problem when he does not even understand the simplest idealization"

  Donald Lynden-Bell

- “Only a fool tries to solve a complicated problem when he does not even understand the simplest idealization”

  Donald Lynden-Bell
- More realistic models: Properties of multi-mass systems poorly reproduced by single-mass models

STRONG MASS SEGREGATION

- “Only a fool tries to solve a complicated problem when he does not even understand the simplest idealization”

  Donald Lynden-Bell
- More realistic models: Properties of multi-mass systems poorly reproduced by single-mass models
- Initial Mass Functions $\in [0.1, \sim 120] M_\odot$ to first order by two (well-separated) mass scales: $\mathcal{O}(1 M_\odot)$ (Main Sequence, White Dwarfs, Neutron Stars) and $\mathcal{O}(10 M_\odot)$ (Stellar Black Holes)

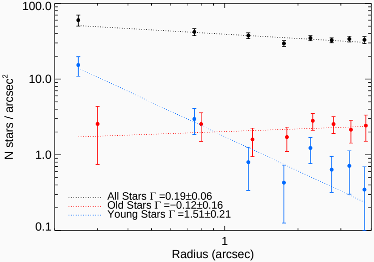
- “Only a fool tries to solve a complicated problem when he does not even understand the simplest idealization”

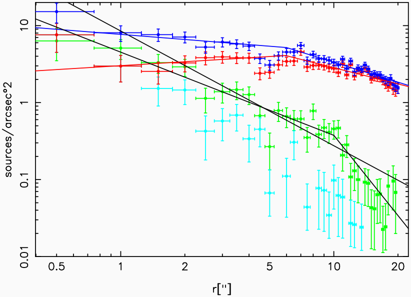
  Donald Lynden-Bell

- More realistic models: Properties of multi-mass systems poorly reproduced by single-mass models
- Initial Mass Functions $\in [0.1, \sim 120] M_{\odot}$ to first order by two (well-separated) mass scales: $\mathcal{O}(1 M_{\odot})$ (Main Sequence, White Dwarfs, Neutron Stars) and $\mathcal{O}(10 M_{\odot})$ (Stellar Black Holes)
- Two branches for the solution: A “weak” (unrealistic) branch and a “strong” branch

  [Hopman & Alexander 2009, Preto & Amaro-Seoane 2010, Amaro-Seoane & Preto 2011]

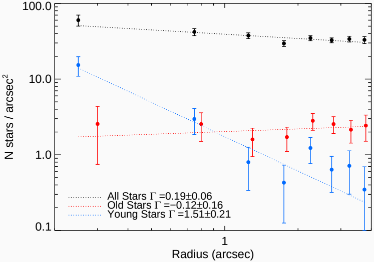
CUSPS IN DISTRESS

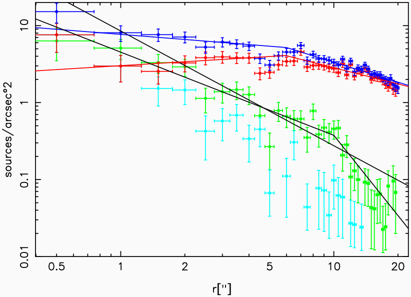




- Deficit of old stars based on number counts of spectroscopically identified, old stars in sub-parsec SgrA* (down to magnitude $K = 15.5$)

[Do et al. 2009, Buchholz et al 2009]



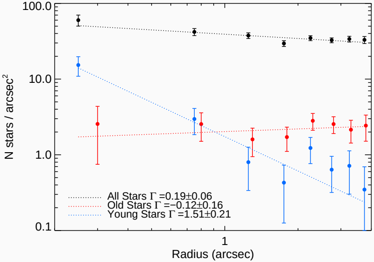


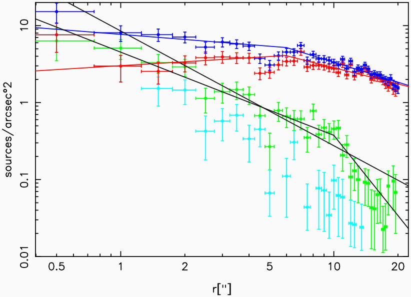
- ▷ Deficit of old stars based on number counts of spectroscopically identified, old stars in sub-parsec SgrA* (down to magnitude $K = 15.5$)

  [Do et al. 2009, Buchholz et al 2009]

- ▷ Best fits seem to favor negative slopes $\gamma < 1$

  [Schödel et al 2009, Chatzopoulos et al 2014]





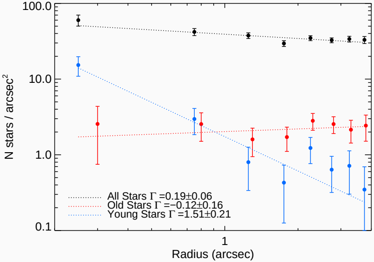
- ▷ Deficit of old stars based on number counts of spectroscopically identified, old stars in sub-parsec SgrA* (down to magnitude $K = 15.5$)

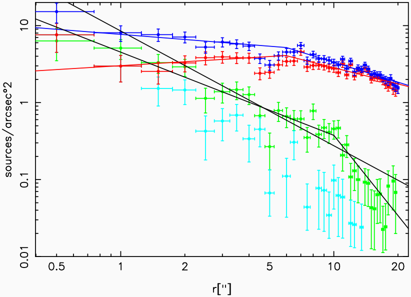
  [Do et al. 2009, Buchholz et al 2009]

- ▷ Best fits seem to favor negative slopes $\gamma < 1$

  [Schödel et al 2009, Chatzopoulos et al 2014]

- ▷ Possibility of a core with $\rho_\star$ decreasing, $\gamma < 0$





- ▷ Deficit of old stars based on number counts of spectroscopically identified, old stars in sub-parsec SgrA* (down to magnitude $K = 15.5$)

  [Do et al. 2009, Buchholz et al 2009]

- ▷ Best fits seem to favor negative slopes $\gamma < 1$

  [Schödel et al 2009, Chatzopoulos et al 2014]

- ▷ Possibility of a core with $\rho_\star$ decreasing, $\gamma < 0$
- ▷ Observers only see essentially late-type giants: Detectable stars are still a small fraction

HOW DO YOU CARVE A HOLE AT THE GALACTIC CENTER?

1. **Infalling clusters carve a hole** – But need a steady inflow of one at roughly every 10^7 years

   [Baumgardt et al 2006, Portegies Zwart et al 2006]

HOW DO YOU CARVE A HOLE AT THE GALACTIC CENTER?

1. **Infalling clusters carve a hole** – But need a steady inflow of one at roughly every 10^7 years

   [Baumgardt et al 2006, Portegies Zwart et al 2006]

2. **SgrA^* is a binary MBH** – But then there must have been a more or less recent major merger involving the Milky Way

HOW DO YOU CARVE A HOLE AT THE GALACTIC CENTER?

1. **Infalling clusters carve a hole** – But need a steady inflow of one at roughly every 10^7 years

   [Baumgardt et al 2006, Portegies Zwart et al 2006]

2. **SgrA^* is a binary MBH** – But then there must have been a more or less recent major merger involving the Milky Way

▷ **Too early** to conclude for the inexistence of a segregated cusp

HOW DO YOU CARVE A HOLE AT THE GALACTIC CENTER?

1. **Infalling clusters carve a hole** – But need a steady inflow of one at roughly every 10^7 years

   [Baumgardt et al 2006, Portegies Zwart et al 2006]

2. **SgrA^* is a binary MBH** – But then there must have been a more or less recent major merger involving the Milky Way

- ▷ **Too early** to conclude for the inexistence of a segregated cusp
- ▷ **Must invoke unlikely events** to get rid of it

HOW DO YOU CARVE A HOLE AT THE GALACTIC CENTER?

1. **Infalling clusters carve a hole** – But need a steady inflow of one at roughly every 10^7 years

   [Baumgardt et al 2006, Portegies Zwart et al 2006]

2. **SgrA^* is a binary MBH** – But then there must have been a more or less recent major merger involving the Milky Way

- ▷ **Too early** to conclude for the inexistence of a segregated cusp
- ▷ **Must invoke unlikely events** to get rid of it
- ▷ **Let's play the game** What is the time necessary for cusp growth if at some point a central core is carved?

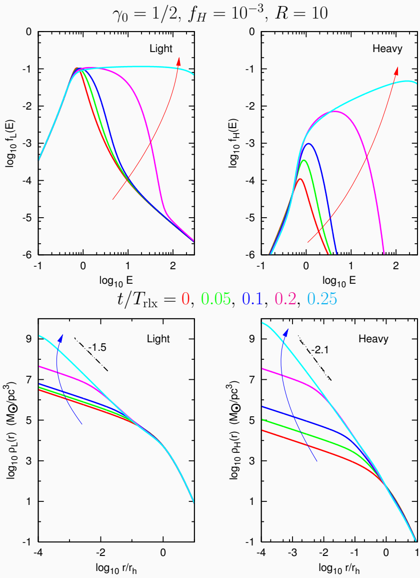
HOW DO YOU CARVE A HOLE AT THE GALACTIC CENTER?

1. **Infalling clusters carve a hole** – But need a steady inflow of one at roughly every 10^7 years

   [Baumgardt et al 2006, Portegies Zwart et al 2006]

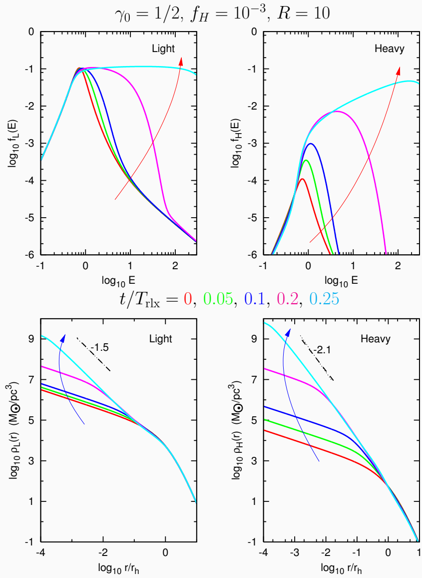
2. **SgrA^* is a binary MBH** – But then there must have been a more or less recent major merger involving the Milky Way

- ▷ **Too early** to conclude for the inexistence of a segregated cusp
- ▷ **Must invoke unlikely events** to get rid of it
- ▷ **Let's play the game** What is the time necessary for cusp growth if at some point a central core is carved?
- ▷ **We have now the correct, more efficient, solution** of mass segregation

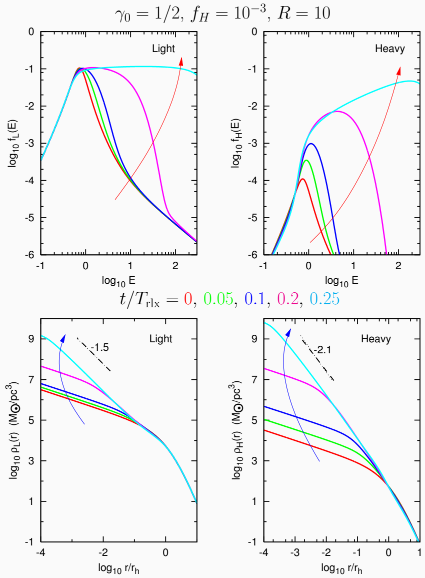


- ▷ By $t \sim 0.25\ T_{\rm rlx}(r_h)$, cusps fully developed ($\sim$ 0.02 pc if scaled to MW)

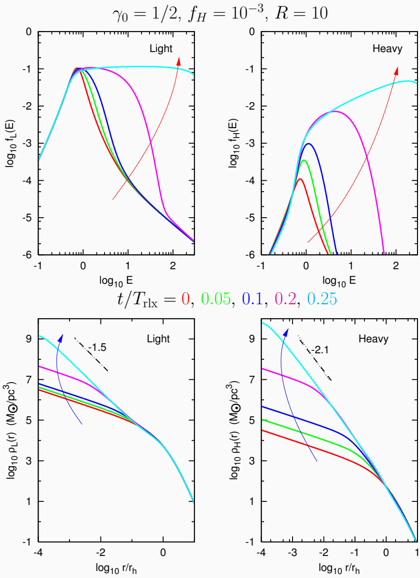
ISOCORE ... REGROWTH



- ▷ By $t \sim 0.25\ T_{\rm rlx}(r_h)$, cusps fully developed ($\sim$ 0.02 pc if scaled to MW)
- ▷ Enough to re-growth very steep cusp of stellar-mass BHs if carving happened more than 6 Gyr ago



- By $t \sim 0.25\ T_{\rm rlx}(r_h)$, cusps fully developed ($\sim$ 0.02 pc if scaled to MW)
- Enough to re-growth very steep cusp of stellar-mass BHs if carving happened more than 6 Gyr ago
- Disagreement with Merritt [Merritt 2009]. Different approach: Neglection of H-H and H-L scattering, valid long as $\rho_H \ll \rho_L$



- By $t \sim 0.25\ T_{\rm rlx}(r_h)$, cusps fully developed ($\sim$ 0.02 pc if scaled to MW)
- Enough to re-growth very steep cusp of stellar-mass BHs if carving happened more than 6 Gyr ago
- Disagreement with Merritt *[Merritt 2009]*. Different approach: Neglection of H-H and H-L scattering, valid long as $\rho_H \ll \rho_L$
- Our results confirmed later *[Gualandris & Merritt 2011]*

WHAT DOES THIS MEAN FOR EMRIS?

- Stellar cusps may re-grow in less than a T_{H} but the existence of cored nuclei still remains a possibility

WHAT DOES THIS MEAN FOR EMRIS?

- Stellar cusps may re-grow in less than a T_{H} but the existence of cored nuclei still remains a possibility
- The Milky Way nucleus is *not* necessarily the prototype of the nucleus from which e-LISA detections will be more frequent

- Stellar cusps may re-grow in less than a T_{H} but the existence of cored nuclei still remains a possibility
- The Milky Way nucleus is *not* necessarily the prototype of the nucleus from which e-LISA detections will be more frequent
- We still expect that a substantial fraction of EMRI events will originate from segregated stellar cusps, in particular with our new solution of mass segregation

DISGUISED CAPTURES

- The EMRI critical radius is very close to the MBH where we do not have many stars

THE ROLE OF THE SPIN

- The EMRI critical radius is very close to the MBH where we do not have many stars
- The bulk of the stellar system outside of the critical radius with orders of magnitude more stars

THE ROLE OF THE SPIN

- The EMRI critical radius is very close to the MBH where we do not have many stars
- The bulk of the stellar system outside of the critical radius with orders of magnitude more stars
- Stars out of the critical radius “plunge” and do not provide us with the kind of information an EMRI does

THE ROLE OF THE SPIN

- The EMRI critical radius is very close to the MBH where we do not have many stars
- The bulk of the stellar system outside of the critical radius with orders of magnitude more stars
- Stars out of the critical radius “plunge” and do not provide us with the kind of information an EMRI does
- Plunges are more frequent than “adiabatic” EMRIs A common result to all event rate estimates

THE ROLE OF THE SPIN

- The EMRI critical radius is very close to the MBH where we do not have many stars
- The bulk of the stellar system outside of the critical radius with orders of magnitude more stars
- Stars out of the critical radius “plunge” and do not provide us with the kind of information an EMRI does
- Plunges are more frequent than “adiabatic” EMRIs A common result to all event rate estimates
- What if these stars did not plunge? We’d have extremely eccentric sources, and event rates orders of magnitude larger

- Number of periapsis passages for an extremely radial stellar black hole before swallowed by the Kerr MBH?

- Number of periapsis passages for an extremely radial stellar black hole before swallowed by the Kerr MBH?
- Not calculated previously but easy to estimate

- Number of periapsis passages for an extremely radial stellar black hole before swallowed by the Kerr MBH?
- Not calculated previously but easy to estimate
- Take initial orbital parameters, evolve them and find the parameters corresponding to a plunge or unstable orbit

- Number of periapsis passages for an extremely radial stellar black hole before swallowed by the Kerr MBH?
- Not calculated previously but easy to estimate
- Take initial orbital parameters, evolve them and find the parameters corresponding to a plunge or unstable orbit
- (p, e, i), calculate constants of motion (E, L_z, C), then the average flux of these "constants", i.e. the average time evolution $(\dot{E}, \dot{L}_z, \dot{C})$

- Number of periapsis passages for an extremely radial stellar black hole before swallowed by the Kerr MBH?
- Not calculated previously but easy to estimate
- Take initial orbital parameters, evolve them and find the parameters corresponding to a plunge or unstable orbit
- (p, e, i), calculate constants of motion (E, L_z, C), then the average flux of these "constants", i.e. the average time evolution $(\dot{E}, \dot{L}_z, \dot{C})$
- Calculate time to go from apo to periapsis and back (radial periode) and thus the change in (E, L_z, C) and so the new constants of motion, therefore: $(p_{\rm new}, e_{\rm new}, i_{\rm new})$

SOME RESULTS DEPENDING ON THE SPIN

$\mathcal{M}_\bullet$	Spin (a/M)	a_0 (pc)	e_i	i (rad)	$\tau_{\rm mrg}$ (yrs)	$\tau_{\rm e-LISA}$	Peri (e-LISA)

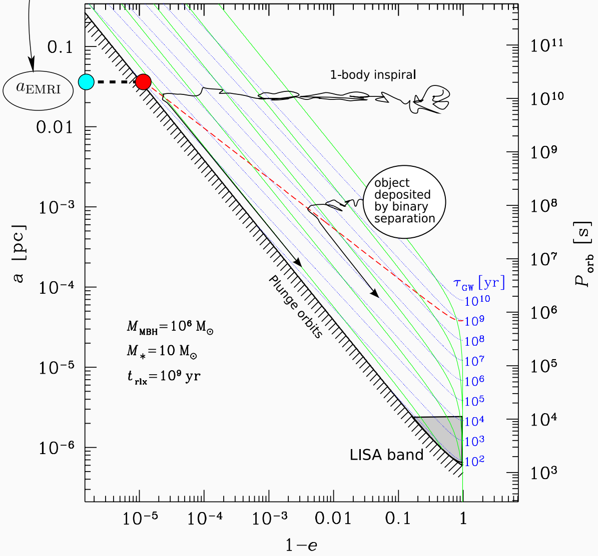
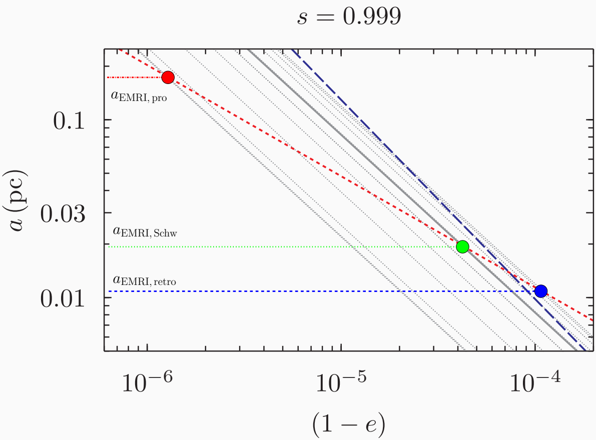
IMPACT OF THE SPIN ON THE RATES?

$$\dot{N}_{\rm EMRI} \simeq \int_0^{a_{\rm EMRI}} \frac{dN_\bullet(a)}{\ln\left(\theta_{\rm LC}^{-2}\right) t_r(a)}$$



$$\dot{N}_{\mathrm{EMRI}} \simeq \int_0^{a_{\mathrm{EMRI}}} \frac{dN_\bullet(a)}{\ln\left(\theta_{\mathrm{LC}}^{-2}\right) t_r(a)}$$



KERR VS. SCHWARZSCHILD

$$a_{\mathrm{EMRI}}^{\mathrm{Kerr}} = a_{\mathrm{EMRI}}^{\mathrm{Schw}} \times \mathcal{W}^{\frac{-5}{6-2\gamma}}(\iota, s)$$

$$\dot{N}_{\mathrm{EMRI}}^{\mathrm{Kerr}} = \dot{N}_{\mathrm{EMRI}}^{\mathrm{Schw}} \times \mathcal{W}^{\frac{20\gamma-45}{12-4\gamma}}(\iota, s)$$

- Take a typical value of a prograde orbit with high spin: $\mathcal{W} = 0.15$; then for a modest $\gamma = 1.5$

$$\dot{N}_{\mathrm{EMRI}}^{\mathrm{Kerr}} \sim 114 \times \dot{N}_{\mathrm{EMRI}}^{\mathrm{Schw}}$$

KERR VS. SCHWARZSCHILD

$$a_{\rm EMRI}^{\rm Kerr} = a_{\rm EMRI}^{\rm Schw} \times \mathcal{W}^{\frac{-5}{6-2\gamma}}(\iota,\, s)$$

$$\dot{N}_{\rm EMRI}^{\rm Kerr} = \dot{N}_{\rm EMRI}^{\rm Schw} \times \mathcal{W}^{\frac{20\gamma-45}{12-4\gamma}}(\iota,\, s)$$

- ▷ Take a typical value of a prograde orbit with high spin: $\mathcal{W} = 0.15$; then for a modest $\gamma = 1.5$

$$\dot{N}_{\rm EMRI}^{\rm Kerr} \sim 114 \times \dot{N}_{\rm EMRI}^{\rm Schw}$$

- ▷ When taking into account spinning MBHs EMRI rates are boosted

THE BUTTERFLY EFFECT

where's the one-star radius?

- What is the radius that contains *one* star?

WHERE'S THE ONE-STAR RADIUS?

- ▷ What is the radius that contains *one* star?
- ▷ Let us use the MW: half of the mass within the orbit of S-2 has $M_{\rm encl}/2 = \eta \times M_\bullet$ with $\eta \leq 0.040$ *[Gillessen et al 2009]*

WHERE'S THE ONE-STAR RADIUS?

- What is the radius that contains *one* star?
- Let us use the MW: half of the mass within the orbit of S-2 has $M_{\rm encl}/2 = \eta \times M_\bullet$ with $\eta \leq 0.040$ *[Gillessen et al 2009]*
- Assume power-law of $R^{-\gamma}$

Where's the one-star radius?

- What is the radius that contains *one* star?
- Let us use the MW: half of the mass within the orbit of S-2 has $M_{\rm encl}/2 = \eta \times M_\bullet$ with $\eta \leq 0.040$ *[Gillessen et al 2009]*
- Assume power-law of $R^{-\gamma}$
- Then

$$M(R) = \int_0^R 4\pi r^2 \rho(r)\, dr \propto \int_0^R r^{-\gamma+2} dr \propto R^{3-\gamma}$$

$$N(R) \simeq 8.6 \times 10^4 \left(\frac{R}{6 \times 10^{-4}\ \rm pc} \right)^{3-\gamma}$$

$$R_1 \simeq 6 \times 10^{-4}\ {\rm pc} \times \left(\frac{1}{8.6 \times 10^4} \right)^{\frac{1}{3-\gamma}}$$

▷ $R_1 \simeq 3 \times 10^{-7}$ pc for $\gamma = 1.5$

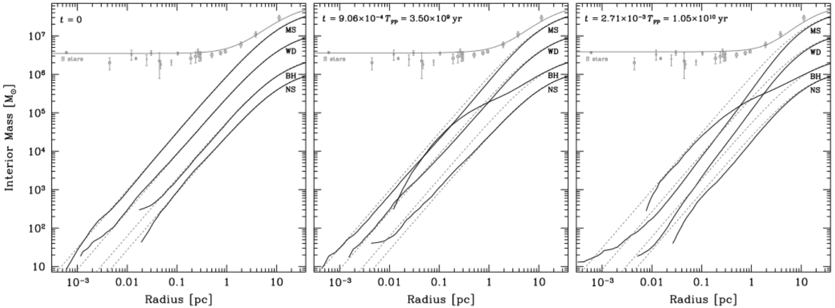


FIG. 11.—Evolution of the profiles of enclosed mass for GN25. The solid lines are the results of the MC simulation. For reference, the dashed lines show $\eta = 1.5$ profiles adjusted on the total mass and half-mass radius of each component. The top thin line is the total mass, including the central MBH; it is compared to the observational constrains for the MW center (see Fig. 3). [*See the electronic edition of the Journal for a color version of this figure.*]

▷ $R_1 \simeq 3 \times 10^{-7}$ pc for $\gamma = 1.5$

▷ $R_1 \ll$ for $\gamma = 2.1$ (our realistic mass segregation models)

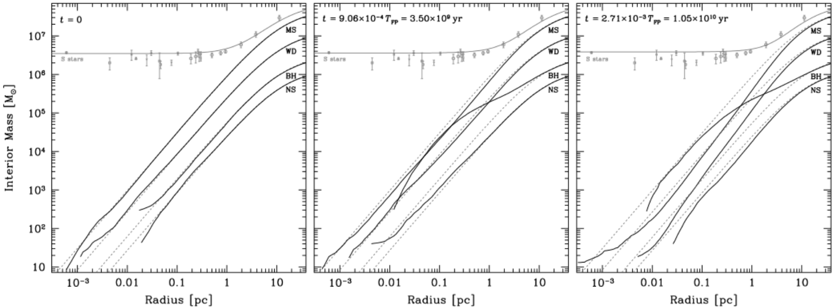

FIG. 11.—Evolution of the profiles of enclosed mass for GN25. The solid lines are the results of the MC simulation. For reference, the dashed lines show $\eta = 1.5$ profiles adjusted on the total mass and half-mass radius of each component. Red $i_\star = 30°$, green $i_\star = 30.001°$, blue fiducial plus a *ten billionth* of a degree, $i_\star = 30.0000000001°$ and magenta plus a *ten trillionth* of a degree, $i_\star = 30.0000000000001°$

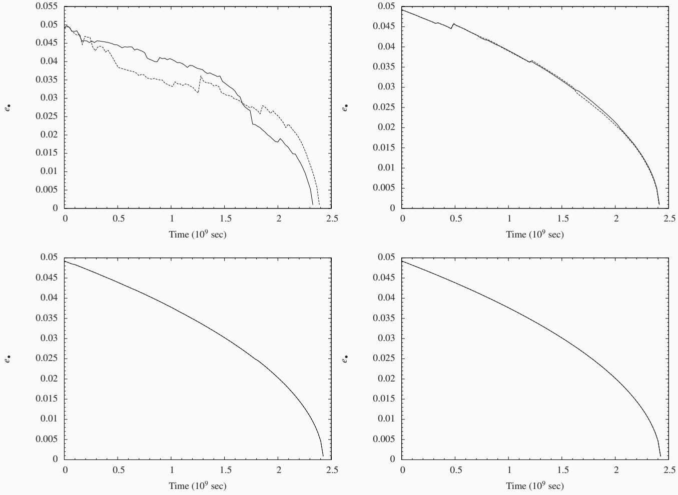
NO, IT'S NOT A BUG



$a_\star = 4 \times 10^{-6}$ pc, 6×10^{-6} pc, 9×10^{-6} pc and 4.07243×10^{-5} pc

CHAOS?

- If at $T = 0$ two orbits differ by some small separation $\xi(0)$ in phase space...

CHAOS?

- If at $T = 0$ two orbits differ by some small separation $\xi(0)$ in phase space...
- ... the difference will grow exponentially *if* the system is chaotic

$$\delta\xi(t) \sim e^{\lambda \Delta T}\xi(0)$$

CHAOS?

- If at $T = 0$ two orbits differ by some small separation $\xi(0)$ in phase space...
- ... the difference will grow exponentially *if* the system is chaotic

$$\delta\xi(t) \sim e^{\lambda \Delta T}\xi(0)$$

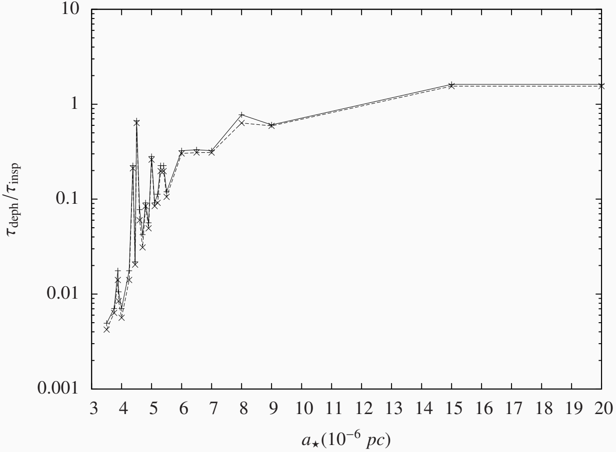
- This is not a classical system

CHAOS?

- If at $T = 0$ two orbits differ by some small separation $\xi(0)$ in phase space...
- ... the difference will grow exponentially *if* the system is chaotic

$$\delta\xi(t) \sim e^{\lambda \Delta T}\xi(0)$$

- This is not a classical system
- How to characterise the chaos?



Start with a fiducial case and another one a *bit* different in phase space. Let them evolve. Calculate time for the "distance" to be $2 \times a_{\bullet}$ and divide it by the isolated inspiral time : Characteristic time

CONCLUSIONS

- A difficult problem: EMRIs closely connected with the dynamics of dense systems

STELLAR DYNAMICS AND EMRIS – CONCLUSIONS

- A difficult problem: EMRIs closely connected with the dynamics of dense systems
- The correct solution of mass segregation leads to enhancement of 1–2 orders of magnitude in rates

STELLAR DYNAMICS AND EMRIS – CONCLUSIONS

- A difficult problem: EMRIs closely connected with the dynamics of dense systems
- The correct solution of mass segregation leads to enhancement of 1–2 orders of magnitude in rates
- Nature's MBH are very likely spinning: Compact objects from very eccentric orbits do not plunge, but become eccentric EMRIs, and dominate the rates

STELLAR DYNAMICS AND EMRIS – CONCLUSIONS

- A difficult problem: EMRIs closely connected with the dynamics of dense systems
- The correct solution of mass segregation leads to enhancement of 1–2 orders of magnitude in rates
- Nature's MBH are very likely spinning: Compact objects from very eccentric orbits do not plunge, but become eccentric EMRIs, and dominate the rates
- Originating in the bulk of the stellar system: Enhanced rates

STELLAR DYNAMICS AND EMRIS – CONCLUSIONS

- A difficult problem: EMRIs closely connected with the dynamics of dense systems
- The correct solution of mass segregation leads to enhancement of 1–2 orders of magnitude in rates
- Nature's MBH are very likely spinning: Compact objects from very eccentric orbits do not plunge, but become eccentric EMRIs, and dominate the rates
- Originating in the bulk of the stellar system: Enhanced rates
- These EMRIs are louder: Larger horizon distance

STELLAR DYNAMICS AND EMRIS – CONCLUSIONS

- A difficult problem: EMRIs closely connected with the dynamics of dense systems
- The correct solution of mass segregation leads to enhancement of 1–2 orders of magnitude in rates
- Nature's MBH are very likely spinning: Compact objects from very eccentric orbits do not plunge, but become eccentric EMRIs, and dominate the rates
- Originating in the bulk of the stellar system: Enhanced rates
- These EMRIs are louder: Larger horizon distance
- Driven by two-body relaxation, a chaotic process: These EMRIs are safe from the so-called Schwarzschild barrier, which blocks most lower-eccentricity EMRIs

STELLAR DYNAMICS AND EMRIS – CONCLUSIONS

- A difficult problem: EMRIs closely connected with the dynamics of dense systems
- The correct solution of mass segregation leads to enhancement of 1–2 orders of magnitude in rates
- Nature's MBH are very likely spinning: Compact objects from very eccentric orbits do not plunge, but become eccentric EMRIs, and dominate the rates
- Originating in the bulk of the stellar system: Enhanced rates
- These EMRIs are louder: Larger horizon distance
- Driven by two-body relaxation, a chaotic process: These EMRIs are safe from the so-called Schwarzschild barrier, which blocks most lower-eccentricity EMRIs
- GR must not always be wrong: It could be an innocent star nearby
