Developments of Physics of Unstable Nuclei YKIS2022b Kyoto, May 23-27, 2022

Mirror energy differences

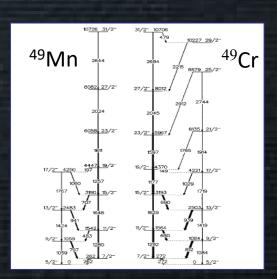

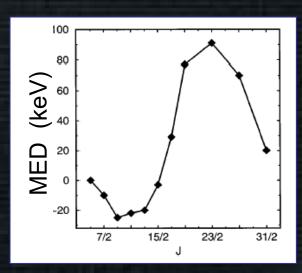

difference in excitation energies

$$\mathrm{MED}_J = \mathrm{E} *_{J,-|T_z|} - \mathrm{E} *_{J,|T_z|}$$

Test the charge symmetry of the interaction $V_{pp} = V_{nn}$

These (small) differences are mainly due to the Coulomb interaction

Measuring MED

Can we reproduce such small energy differences in the shell model framework?

What can we learn from them?

They contain a richness of information about spin-dependent structural phenomena

We measure **nuclear** structure features:

- How the nucleus generates its angular momentum
- Evolution of radii (deformation) along a rotational band
- Learn about the configuration of the states
- Isospin non-conserving terms of the interaction
- Estimate the neutron skin

Nuclear radius and skin

Proton and neutron radii tend to keep similar

First part: we neglect the skin and calculate the radius as the average of proton and neutron radii to predict the MED

Second part: we use the measured MED to estimate the nucleon skin for every excited state

Contributions to the MED

We start from diagonalizing a nuclear hamiltonian that conserves isospin and treat Coulomb and other eventual isospin symmetry breaking (ISB) contributions perturbatively

$$V_C + V_B = V_{Cm} + V_{CM} + V_B$$

monopole Coulomb

 represents a spherical mean field extracted from the interacting shell model

 determines the single particle energies and the shell evolution

Multipole Coulomb

- correlations
- energy gains

Isospin symmetry breaking term of non-Coulomb origin

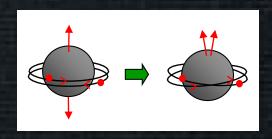

Calculation of the MED

$$MED_{J}^{theo} = \Delta \langle V_{CM} \rangle_{J} + \Delta \langle V_{Cm} \rangle_{J} + \Delta \langle V_{B} \rangle_{J}$$

V_{CM} Multipole part of the Coulomb energy →

Between valence protons only

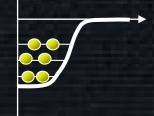

V_{Cm} monopole part of the Coulomb ⁻ energy radial effect: radius changes with J

ℓ·ℓ term to account for shell effects

l⋅s electromagnetic spin-orbit term

change the single-particle energies

V_B Isospin symmetry breaking term

$$V_{\pi\pi}^{J=0} - V_{\nu\nu}^{J=0} = -100 \text{ keV}$$

for all orbits

The radial term

Coulomb energy of a charged sphere:

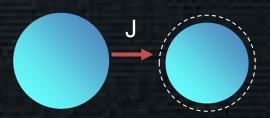

$$E_C = \frac{3Z(Z-1)e^2}{5R_C}$$

The difference between the energy of the ground states:

$$\Delta E_C(J=0) = E_C(Z_>) - E_C(Z_<) = \frac{3n(2Z_> - n)e^2}{5R_C}$$

 $T_z = \pm \frac{n}{2}$

If R_C changes as a function of the angular momentum...

$$\Delta E_{Cr}(J) = \Delta E_{C}(J) - \Delta E_{C}(0) = \frac{3}{5}n(2Z_{>} - n)e^{2}\left(\frac{R_{C}(0) - R_{C}(J)}{R_{C}^{2}}\right)$$

$$= -\frac{3}{5}n(2Z_{>} - n)e^{2}\frac{\Delta R_{C}(J)}{R_{C}^{2}} = nC \cdot \Delta R_{C}(J)$$

Radial contribution to the MED

The radial effect with the shell model

The radius of a nucleus depends on the occupation of the different orbitals and in the fp shell p orbits have larger radius than f orbits.

The radial term will depend on the change of occupation of the p orbitals as a function of J

$$V_{Cm,r}(J) = 2|T_z|\alpha \left\langle \frac{\Delta z_p + \Delta n_p}{2} \right\rangle_J$$

radial monopole term

 $\Delta z_{\rm p}$ and $\Delta n_{\rm p}$ are the number of protons and neutrons in the p orbits, relative to the g.s. (J=0)

 α is not a free parameter but can be estimated from experimental data:

The radial parameter amounts to $\alpha \sim 200 \text{ keV}$ for nuclei in the $f_{7/2}$ shell

Calculating the MED with SM

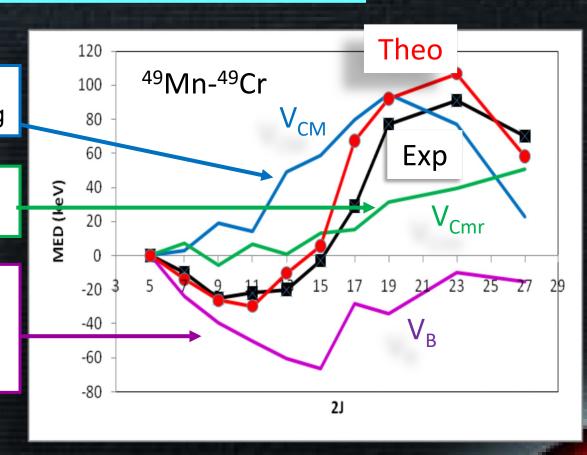

$$MED_{J}^{theo} = \Delta \left(\langle V_{CM} \rangle_{J} + \langle V_{Cm} \rangle_{J} + \langle V_{B} \rangle_{J} \right)$$

VCM: gives information on the nucleon alignment or recoupling

VCmr: gives information on changes in the nuclear radius

Important contribution from the ISB VB term:

of the same order as the Coulomb contributions

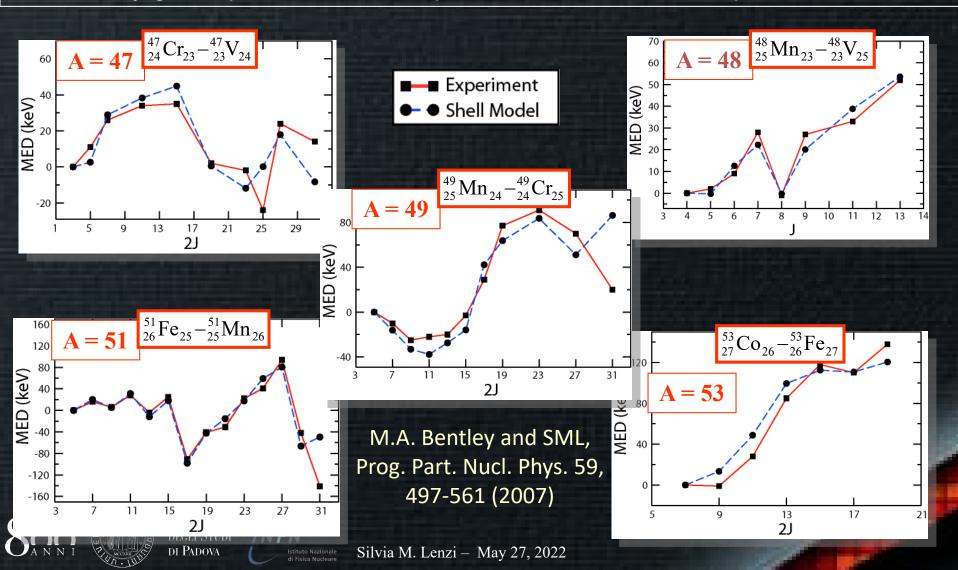

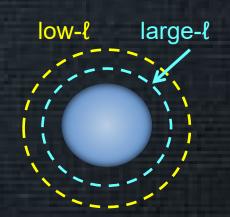

MED in the $f_{7/2}$ shell

Very good quantitative description of data without free parameters

The size of the orbital radius

In a main shell, the radial extension of low-\ell orbits is much larger that the others

A similar behavior is predicted in the fp shell: when the *p* orbits are occupied by one or more nucleons, the orbital radius decreasses.

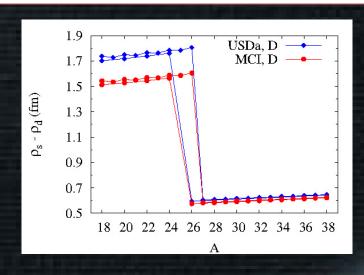

$$V_{Cm,r}(J) = 2|T_z|\alpha \left\langle \frac{\Delta z_p + \Delta n_p}{2} \right\rangle_J$$

$$\alpha \approx 200 \text{ keV for } (z_p + n_p) < 1$$

 $\alpha \approx 50 \text{ keV for } (z_p + n_p) \ge 1$

In the sd shell Bonnard and Zuker have found a very peculiar behaviour of the 1s_{1/2} orbit:

$$r_s - r_d \approx 1.6 \text{ fm}$$
 $Z, N \le 14$
 $r_s - r_d \approx 0.6 \text{ fm}$ $Z, N > 14$

J. Bonnard and A. P. Zuker, JoP Conf. Series 1023 (2018) 012016

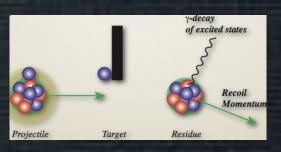

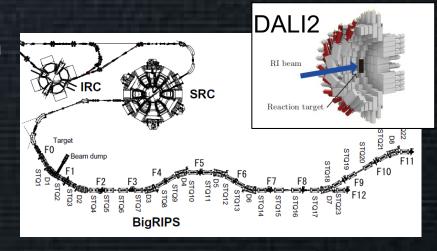

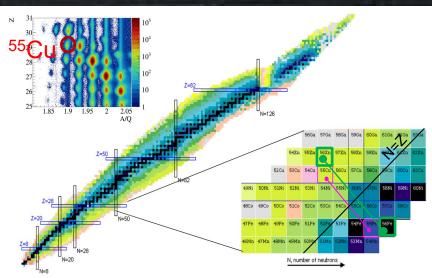

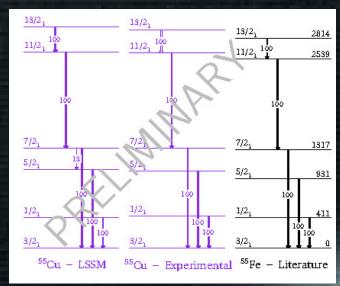

MED in T=3/2 and T=2

Knockout reactions at relativistic energy Need high efficiency of gamma detection for large T mirror pairs

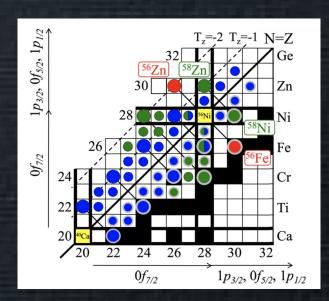

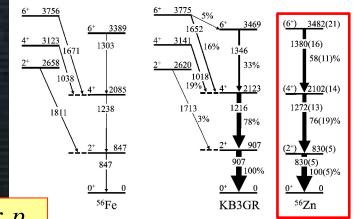

MED in T=2 A=56 mirrors

Excited states in ⁵⁶Zn (T=2) have been populated for the first time

The role of the radial term increasses with T

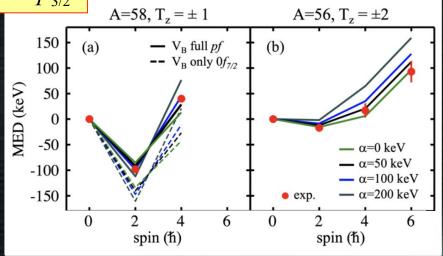

$$V_{Cm,r}(J) = 2 \left(T_z \middle| \alpha \right) \left(\frac{\Delta z_p + \Delta n_p}{2} \right)_J$$

 $\alpha = 200 \text{ keV for } p_{1/2}$

 $\alpha = 50 \text{ keV for } p_{3/2}$

A. Fernandez et al., Physics Letters B 823 (2021) 136784

The radius of the low- ℓ orbits decreases when they are occupied by one or more nucleons.

Recent MED data for T=3/2 A=55, 61, 73 and T=1 A=62, 70, confirm these conclusions

We will now use the MED data to deduce the nuclear skin

Charge radii and nuclear skin

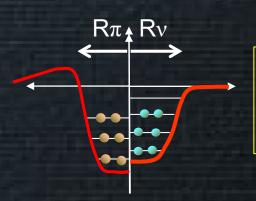

Charge radii are usually measured via electron scattering.

These measurements are limited to stable nuclei.

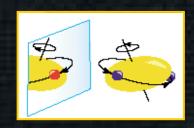

Neutron skin is still more difficult to measure.

Laser spectroscopy allows to measure radial shifts along isotopic chains.

This applies to ground states or isomeric states.

Can we get any information on the evolution of radii in excited states and on the neutron skin?

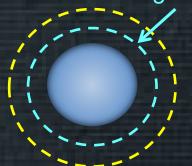

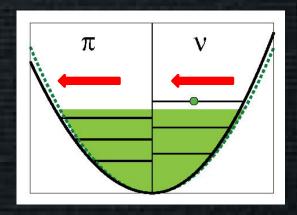

Proton and neutron radii

Studying mirror energies in doubly-magic nuclei + 1 nucleon

Isovector monopole polarizability

The addition of a nucleon induces changes in the potential wells of both protons and neutrons and tends to equalize the radii

$\Delta r_{v\pi}$ (fm) J^{π} A 5/2+ 17 0.056 1/2+ 0.147 41 7/2 0.015 5/2-0.018 3/2-0.038 1/2 0.037

Radii and MED

The size parameters are determined using:

- the charge radius of the neutron-rich partner
- the MED
- Isospin-symmetry arguments

$$\langle r_{\pi,\nu}^2 \rangle \propto \frac{1}{\hbar \omega_{\pi,\nu}}$$

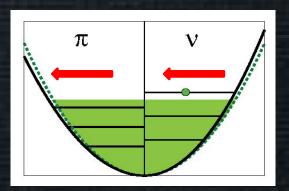

measured!

$$r_{\pi}(N > Z) = r_{\nu}(N < Z)$$
 isospin symmetry

The charge radius of the proton-rich partner is obtained from the MED

$$r_{\pi}(N < Z) = r_{\nu}(N > Z)$$

J. Bonnard et al., PRL 116, 212501 (2016)

Due to the isovector monopole polarization, we need to determine the size of both potential wells to calculate the matrix elements of the effective interaction to calculate the MED. They are different for protons and neutrons!

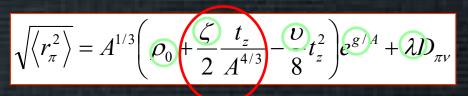

MED and neutron skin

Using a 5-parameter fit of measured charge radii for A<60

J. Duflo, A. P. Zuker, PRC 66, 051304 (2002)

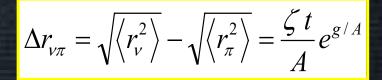

compute the matrix elements of a realistic CD interaction

Calculate the MED

Vary ζ to match the experimental MED

Obtain the neutron skin

Example: for nuclei with one nucleon over a doubly-closed shell nucleus, the neutron skin varies linearly with the ζ parameter

J. Bonnard et al., PRL 116, 212501 (2016)

Α	J^π	$\Delta r_{v\pi}$ (fm)	ζ (fm)	
17	5/2+	0.056	0.90	C
	1/2+	0.147	2.37	S
41	7/2-	0.015	0.61	J
	5/2 ⁻	0.018	0.71	J
	3/2-	0.038	1.50	ľ
	1/2-	0.037	1.48	ľ

The procedure

Use the information on the measured charge radii and differences in the binding energy of the mirror nuclei

Use the Duflo-Zuker formula to obtain the size parameters for protons and neutrons

$$\left\langle r_{\pi,\nu}^{2}\right\rangle \propto \frac{1}{\hbar \omega_{\pi,\nu}}$$

calculate the matrix elements of the realistic interaction

Vary the ξ parameter and fit all available data on charge radii for A<60

Compute the MED with shell model and compare with data

obtain the neutron skin

$$\Delta r_{v\pi} = \frac{\zeta t}{A} e^{g/A}$$

MED and neutron skin in A=23

The MED depend linearly on the value of the nucleon skin

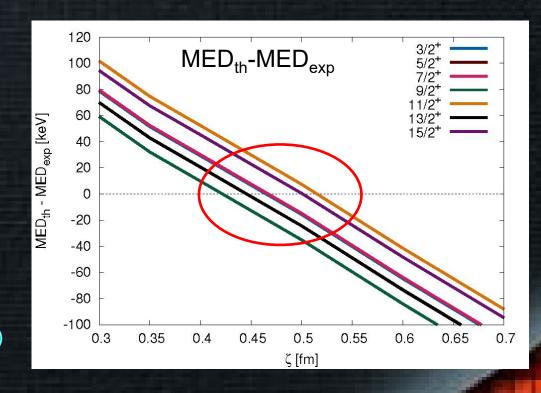

neutron skin

$$\Delta r_{\nu\pi} = \sqrt{\langle r_{\nu}^{2} \rangle} - \sqrt{\langle r_{\pi}^{2} \rangle} = \bigcirc f(A, T)$$

J. Duflo, A. P. Zuker, PRC 66, 051304 (2002)

We vary ζ to match the experimental MED

A. Boso *et al.*, Phys. Rev. Lett. 121, 032502 (2018)

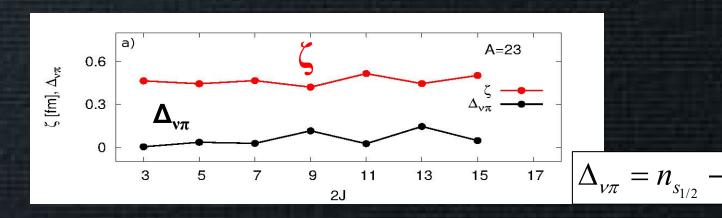

MED and neutron skin

For ²³Na we obtain the neutron skin (in fm):

J	3/2	5/2	7/2	9/2	11/2	13/2	15/2
$\Delta r_{ u\pi}$	0.0211	0.0202	0.0211	0.0192	0.0233	0.0202	0.0226

Interestingly, the skin is correlated with the difference of occupation number of neutrons minus protons $\Delta_{v\pi} \text{ in the low-}\ell \text{ orbit } s_{1/2}!$

A. Boso et al., Phys. Rev. Lett. 121, 032502 (2018)

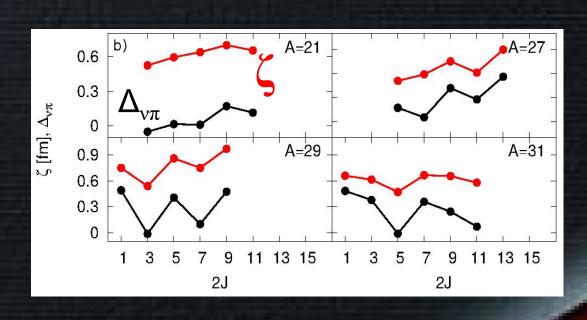

Correlation between skin and difference of occupation numbers

We apply this procedure to the MED for nuclei in the sd shell and deduce the value of the skin for each excited state

In all cases, the skin is correlated with the difference of occupation number of neutrons minus protons $(\Delta_{v\pi})$ in the $s_{1/2}$ orbit!

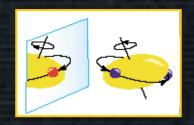

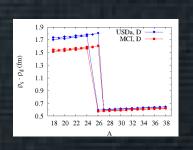

A. Boso *et al.*, Phys. Rev. Lett. 121, 032502 (2018)

What have we learned?

The MED are sensitive to the nuclear structure and therefore constitute a very powerful tool to understand several nuclear properties.

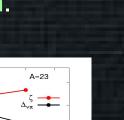

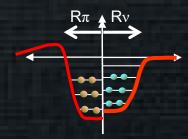

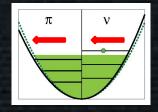

In particular, MED depend on the nuclear radius (average of protons and neutrons). Low- ℓ orbits reduce their radius with occupancy.

MED can give us information on the nuclear skin.

There is a strong correlation between the skin and the difference of occupation of neutrons and protons of the low- ℓ orbit.

Special thanks to

J.Bonnard, A. Boso, M.A. Bentley, A. Jungclaus, F. Recchia, D. Rudolph, and A.P. Zuker

Thank you for your attention

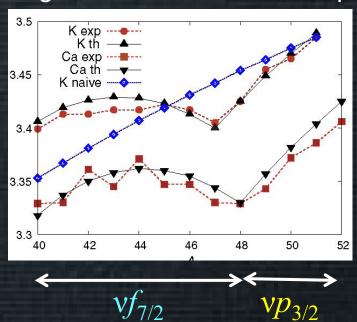

Charge radii

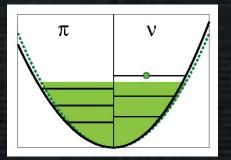

Charge radii in Ca and K isotopes

Proton radii increases when filling with neutrons the p_{3/2} shell!

J. Bonnard et al., PRL 116, 212501 (2016)

The addition of a nucleon induces changes in the potential wells of both protons and neutrons

Theoretical curves obtained from a 5-parameter fit of measured charge radii for A<60

$$r_{\pi} = A^{1/3} \left(r_0 + \frac{\zeta}{2} \frac{t_z}{A^{4/3}} - \frac{\upsilon}{2} \left(\frac{t_z}{2} \right)^2 \right) e^{g/A} + \lambda D_{\pi \nu}$$
