SN2013dqy

# Flash ionization

Credit; Dan Perley

- First signatures of CSM- few hrs to days
- Number of narrow emission lines from highly ionized species - flash ionization
- Ionization of CSM at shock breakout - earliest traces of CSM (Gal-Yam et al. 2014, Khazov et al. 2016, Kochanek 2019)
- Radiation driven process - Produced before sustained shock interaction turns on.
- Disappear within few days - confined CSM (Khazov+16)
- Mass loss rate  $\sim 10^{-3} M_{\odot} \text{ yr}^{-1}$ . Denser CSM extending to  $<10^{15} \text{ cm}$

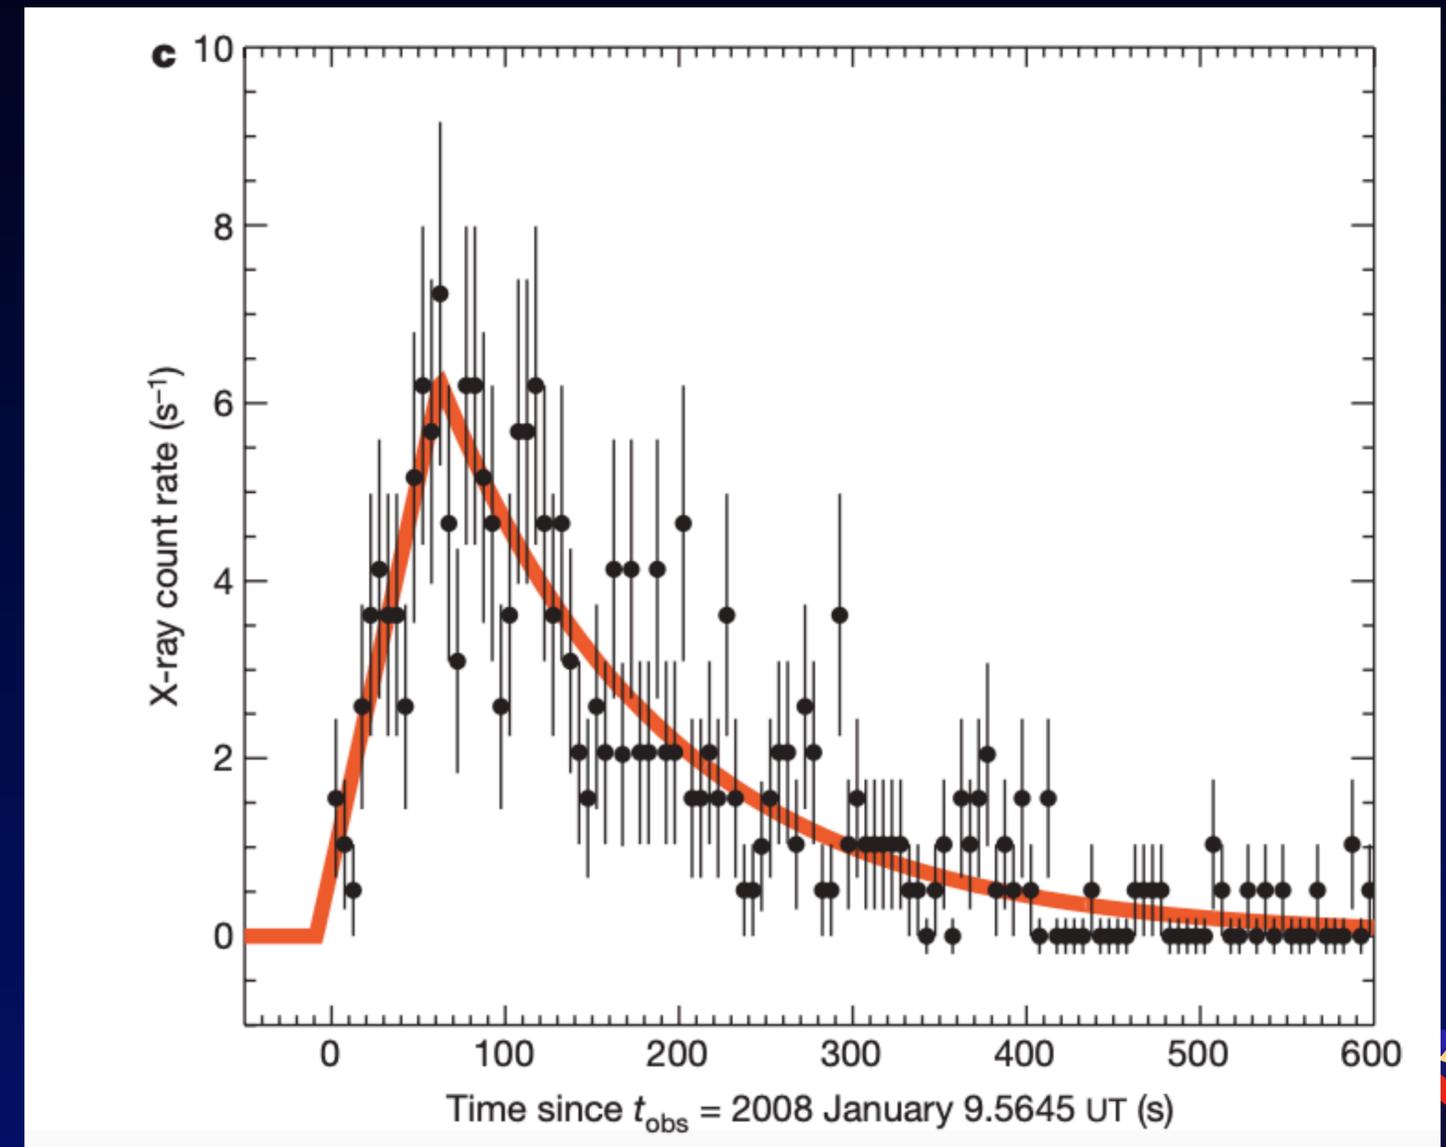

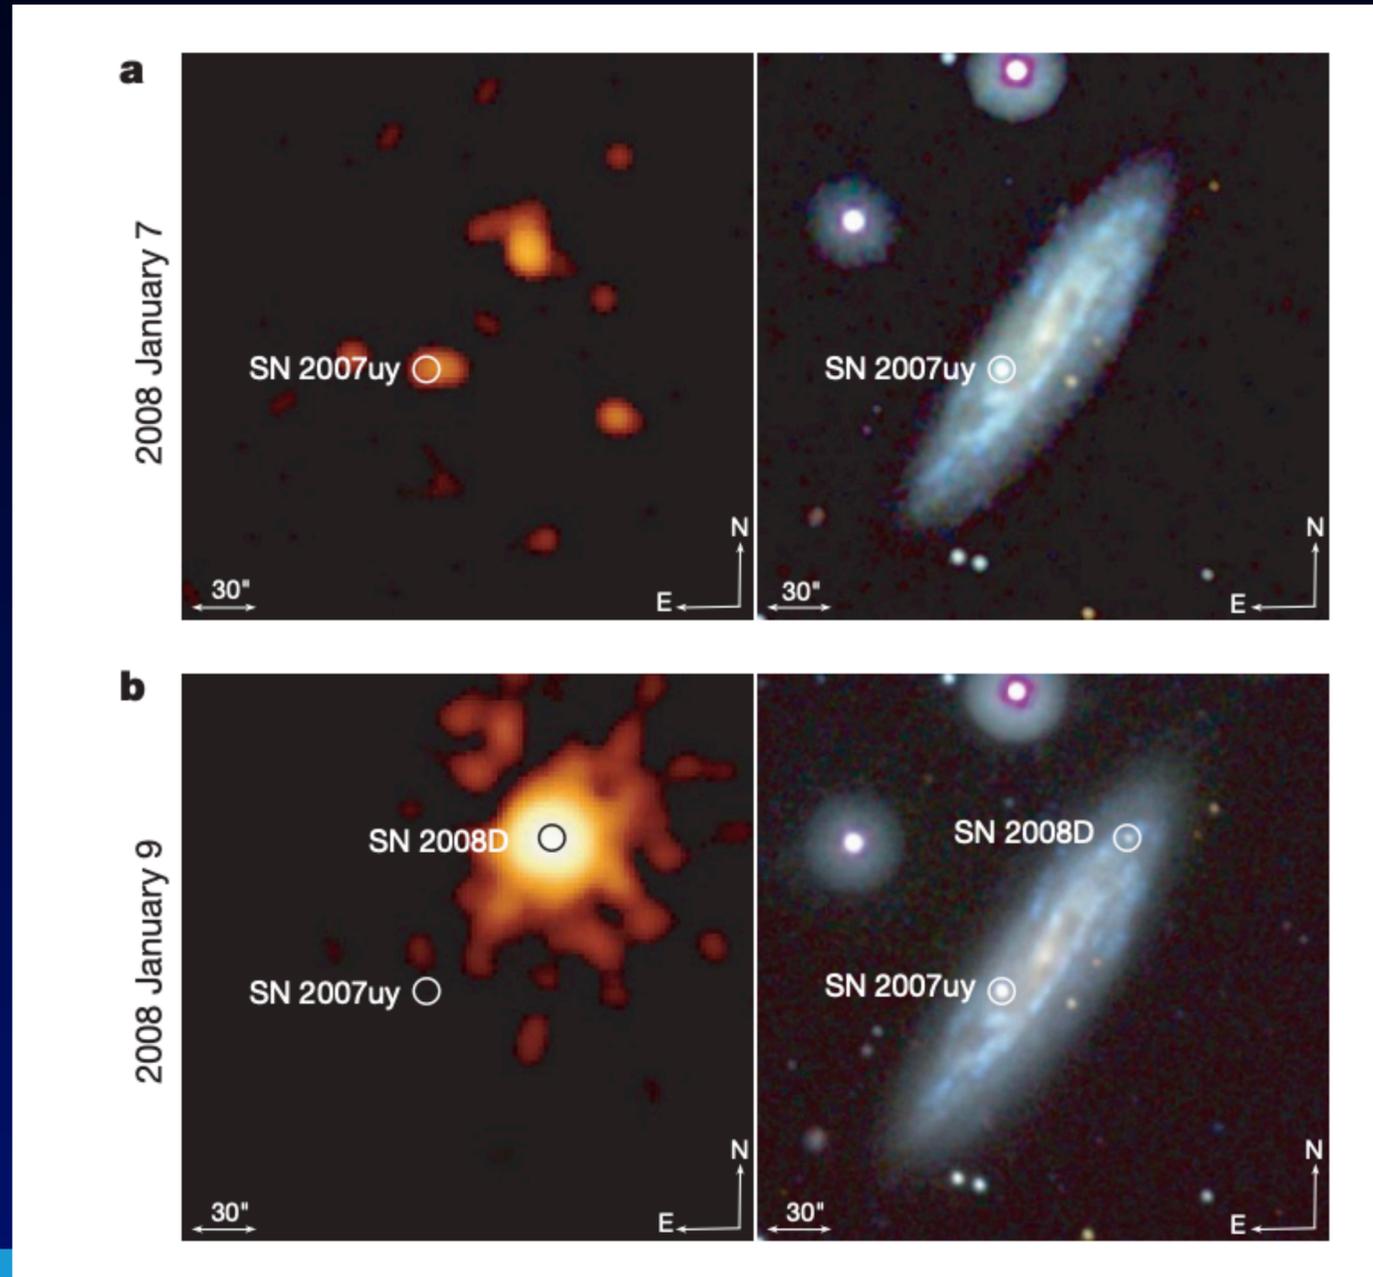

# A note on flash ionization

SN	Sub-type	First FI	Representative FI lines
SN 2006bp	IIP	+2 d	He II ( $\lambda 4200, \lambda 4686\text{\AA}$ ), C IV ( $\lambda 5805\text{\AA}$ )
SN 2013fs	IIP	+0.3 d	He II ( $\lambda 4686\text{\AA}$ ), N V ( $\lambda\lambda 4604, 4620\text{\AA}$ ), N III & C III ( $\lambda\lambda 4634, 4640\text{\AA} / \lambda\lambda 4647, 4650\text{\AA}$ ), O IV/V/VI
SN 2014G	IIL	2–3 d	He II ( $\lambda 4686\text{\AA}$ ), C IV $\lambda 5803$ , N III, IV ( $\lambda\lambda 4640\text{\AA}, \lambda\lambda 4057, 5201, 7113\text{\AA}$ )
SN 2016bkv	low-lum. IIP	$\leq 5$ d	H ( $\lambda 4101, \lambda 4340, \lambda 4861, \lambda 6563\text{\AA}$ ), He II ( $\lambda 4686, \lambda 5411\text{\AA}$ ), C III/N III blend
SN 2017ahn	fast-decl. II	+1 d	Narrow Balmer series, He II $\lambda 4686$
SN 2020pni	II	+1 d	H $\alpha$ , He II, C III/N III blend
SN 2020tlf	II-P/L	+0.7 d	Narrow symmetric H I and He II lines
SN 2022acko	low-lum. IIP	+2 d	He II $\lambda 4686$ , C III
SN 2022jox	II	+0.8 d	H I, He II, C IV, N IV
SN 2023ixf	IIP	+0.4 d	He II $\lambda 4686$ , C IV $\lambda\lambda 5801, 5812$ , N V $\lambda\lambda 4603, 4619$
SN 2024ggi	IIP	+0.8 d	He II $\lambda 4686$ , C IV $\lambda\lambda 5801, 5812$ , N IV $\lambda\lambda 7109, 7123$ , O V $\lambda 5590$

- Flash ionization signatures mostly in Type II supernovae
- Stripped envelope supernovae - very fast evolution, no nearby CSM
- Not usually seen in type IIn supernovae - so dense that the breakout radiation is trapped and shock interaction dominates from the start.
- Perfect amount of CSM needed!!!

# Connecting shock breakout to flash ionization

SN 2008D - Soderberg, ... PC ... 2008

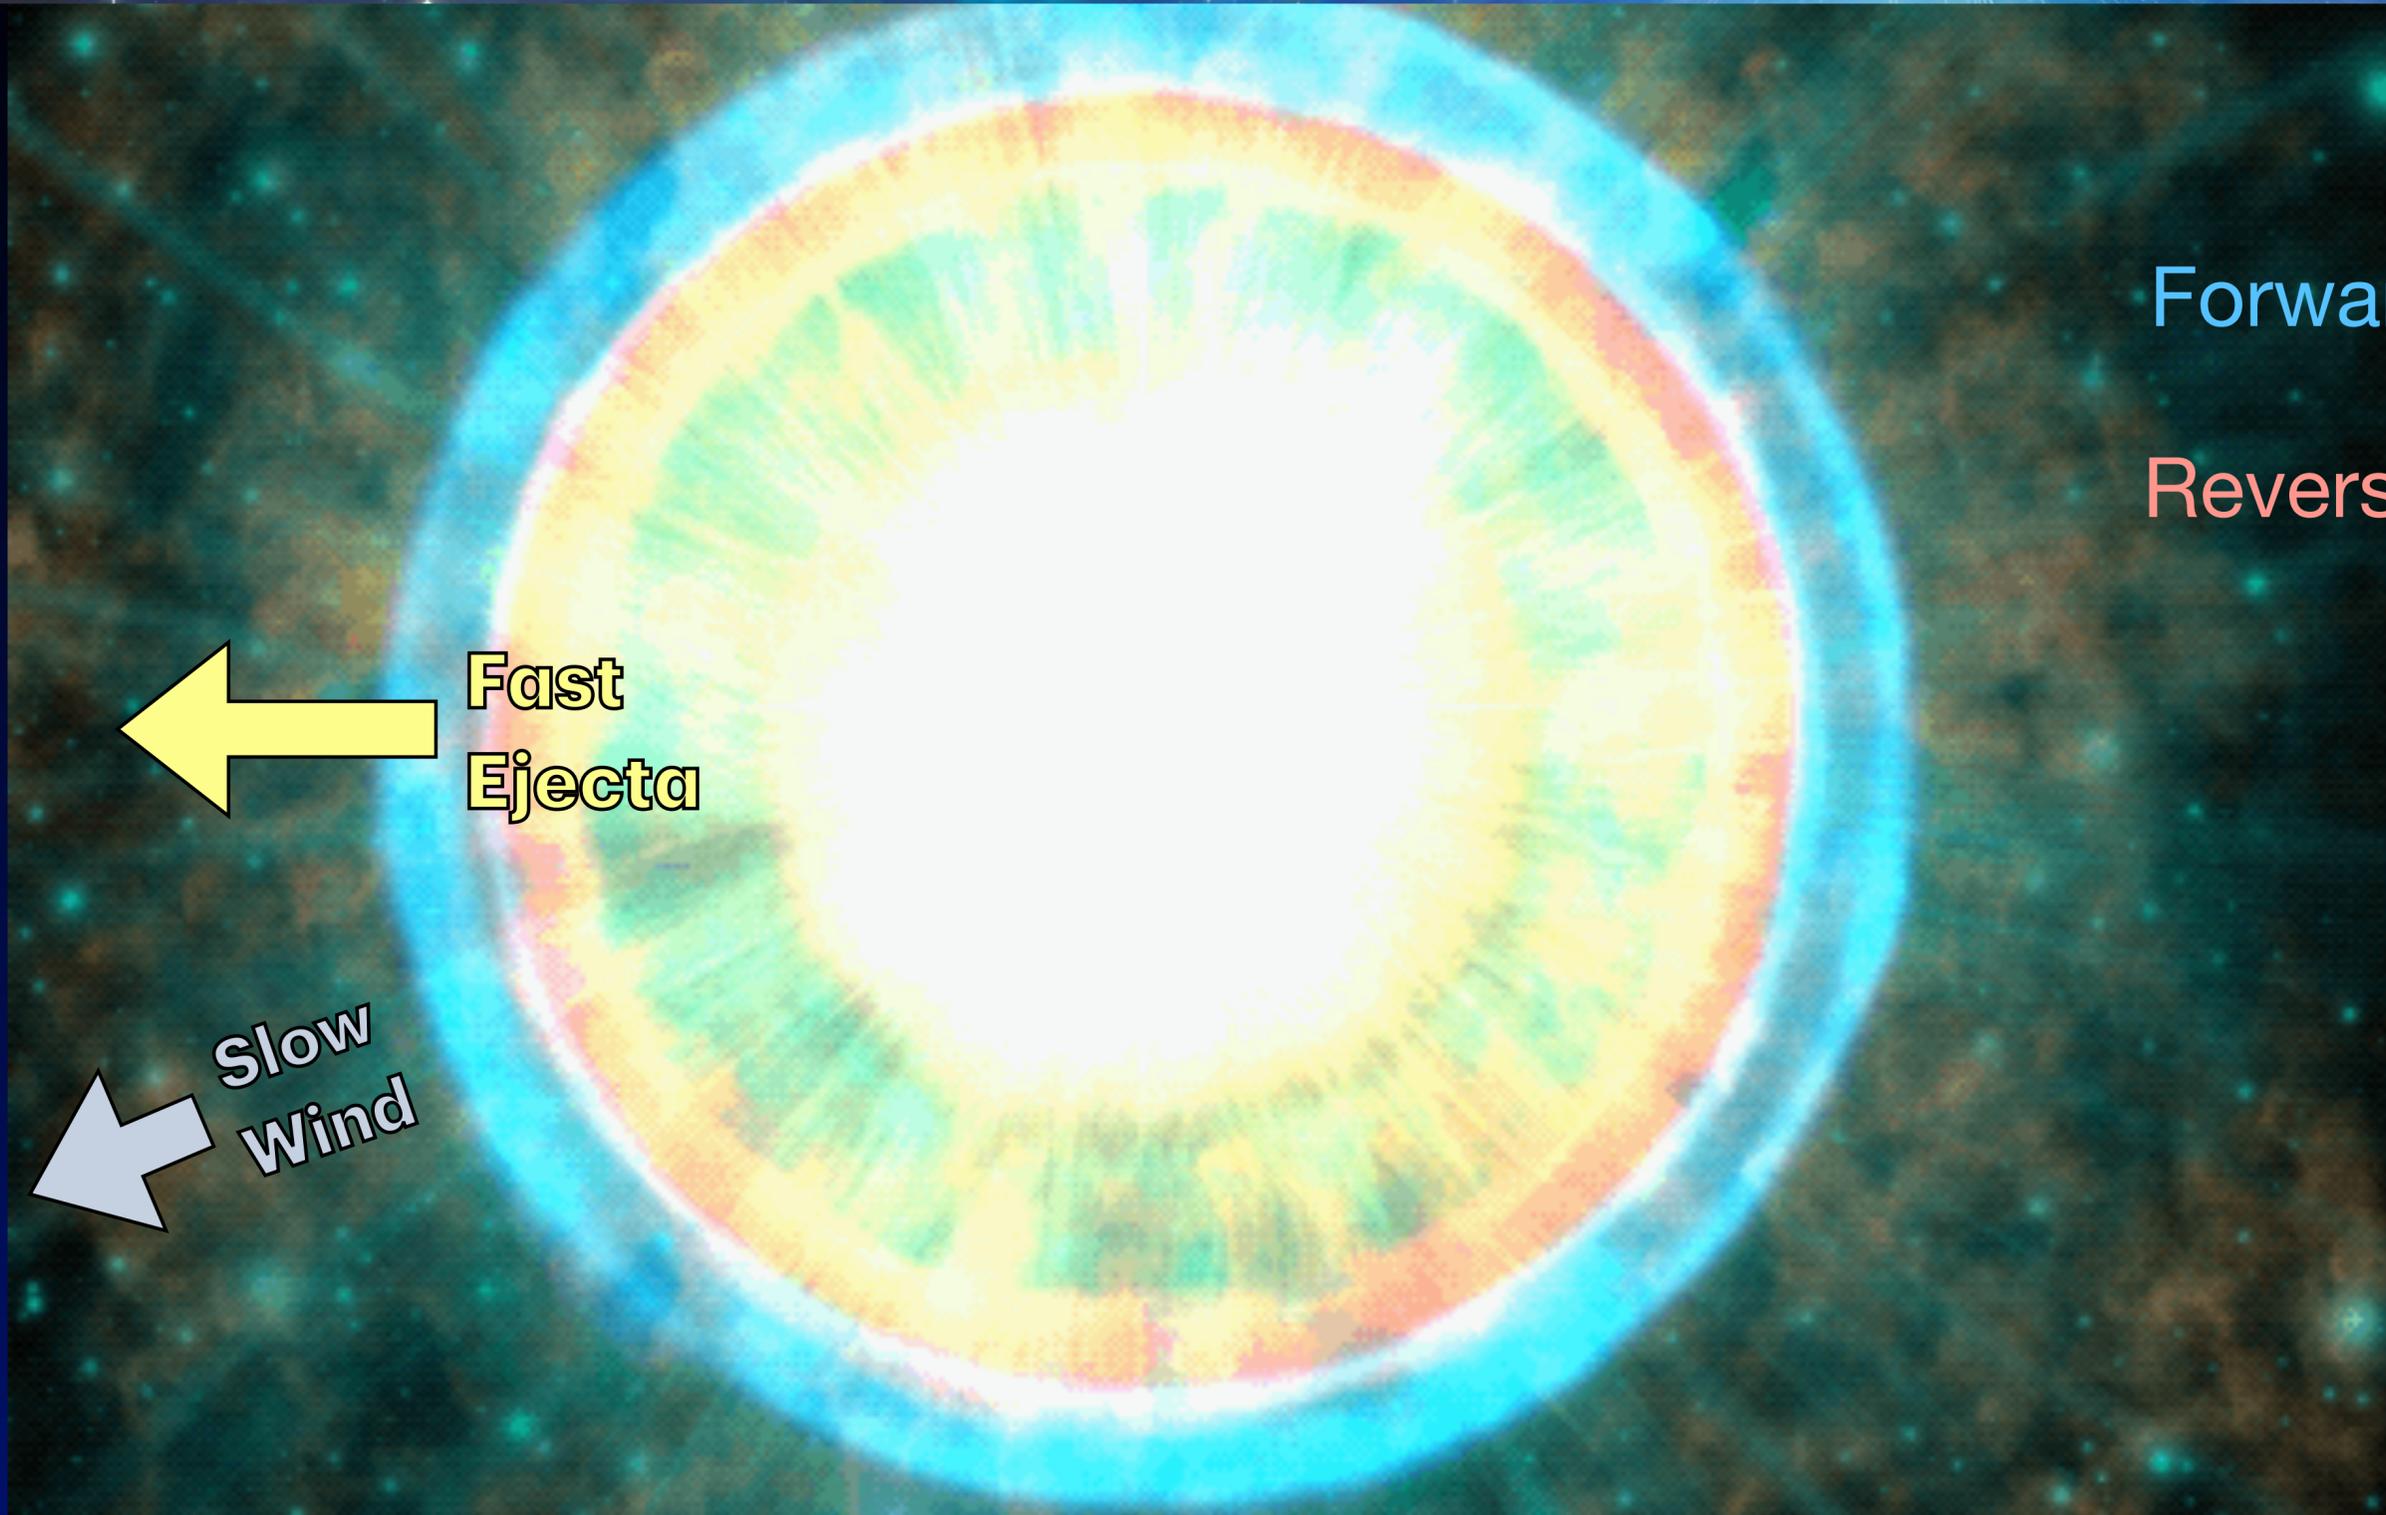

Soderberg, ... PC ... 2008

# Connecting shock breakout to flash ionization

SN 2008D - Soderberg, ... PC ... 2008, Why no flash spectra?

- X-ray outburst was the ionizing radiation.
- Why no flash spectra?
- Ib supernova - very fast evolution of shock breakout
- Non-favorable CSM geometry
- Very little CSM - even with non-negligible mass loss, the **column density can be small** due to large wind speed.
- Optically thick compact CSM, no radiation did not come out.

# Circumstellar Interaction - collision of ejecta to CSM

Forward Shock

Reverse Shock

Fast Ejecta

Slow Wind

# Circumstellar Interaction - collision of ejecta to CSM

Flash ionization - **months - years** of mass loss  
CS interaction traces **years–centuries** of mass loss

Ejecta

Flash ionization is the “UV photograph” of the progenitor’s final days; sustained CSI is the long-exposure movie of its mass-loss history.

# Circumstellar interaction

Energy conversion: kinetic  $\rightarrow$   
thermal  $\rightarrow$  non-thermal  $\rightarrow$  radiation

Radius = look-back time;  
density = conversion efficiency

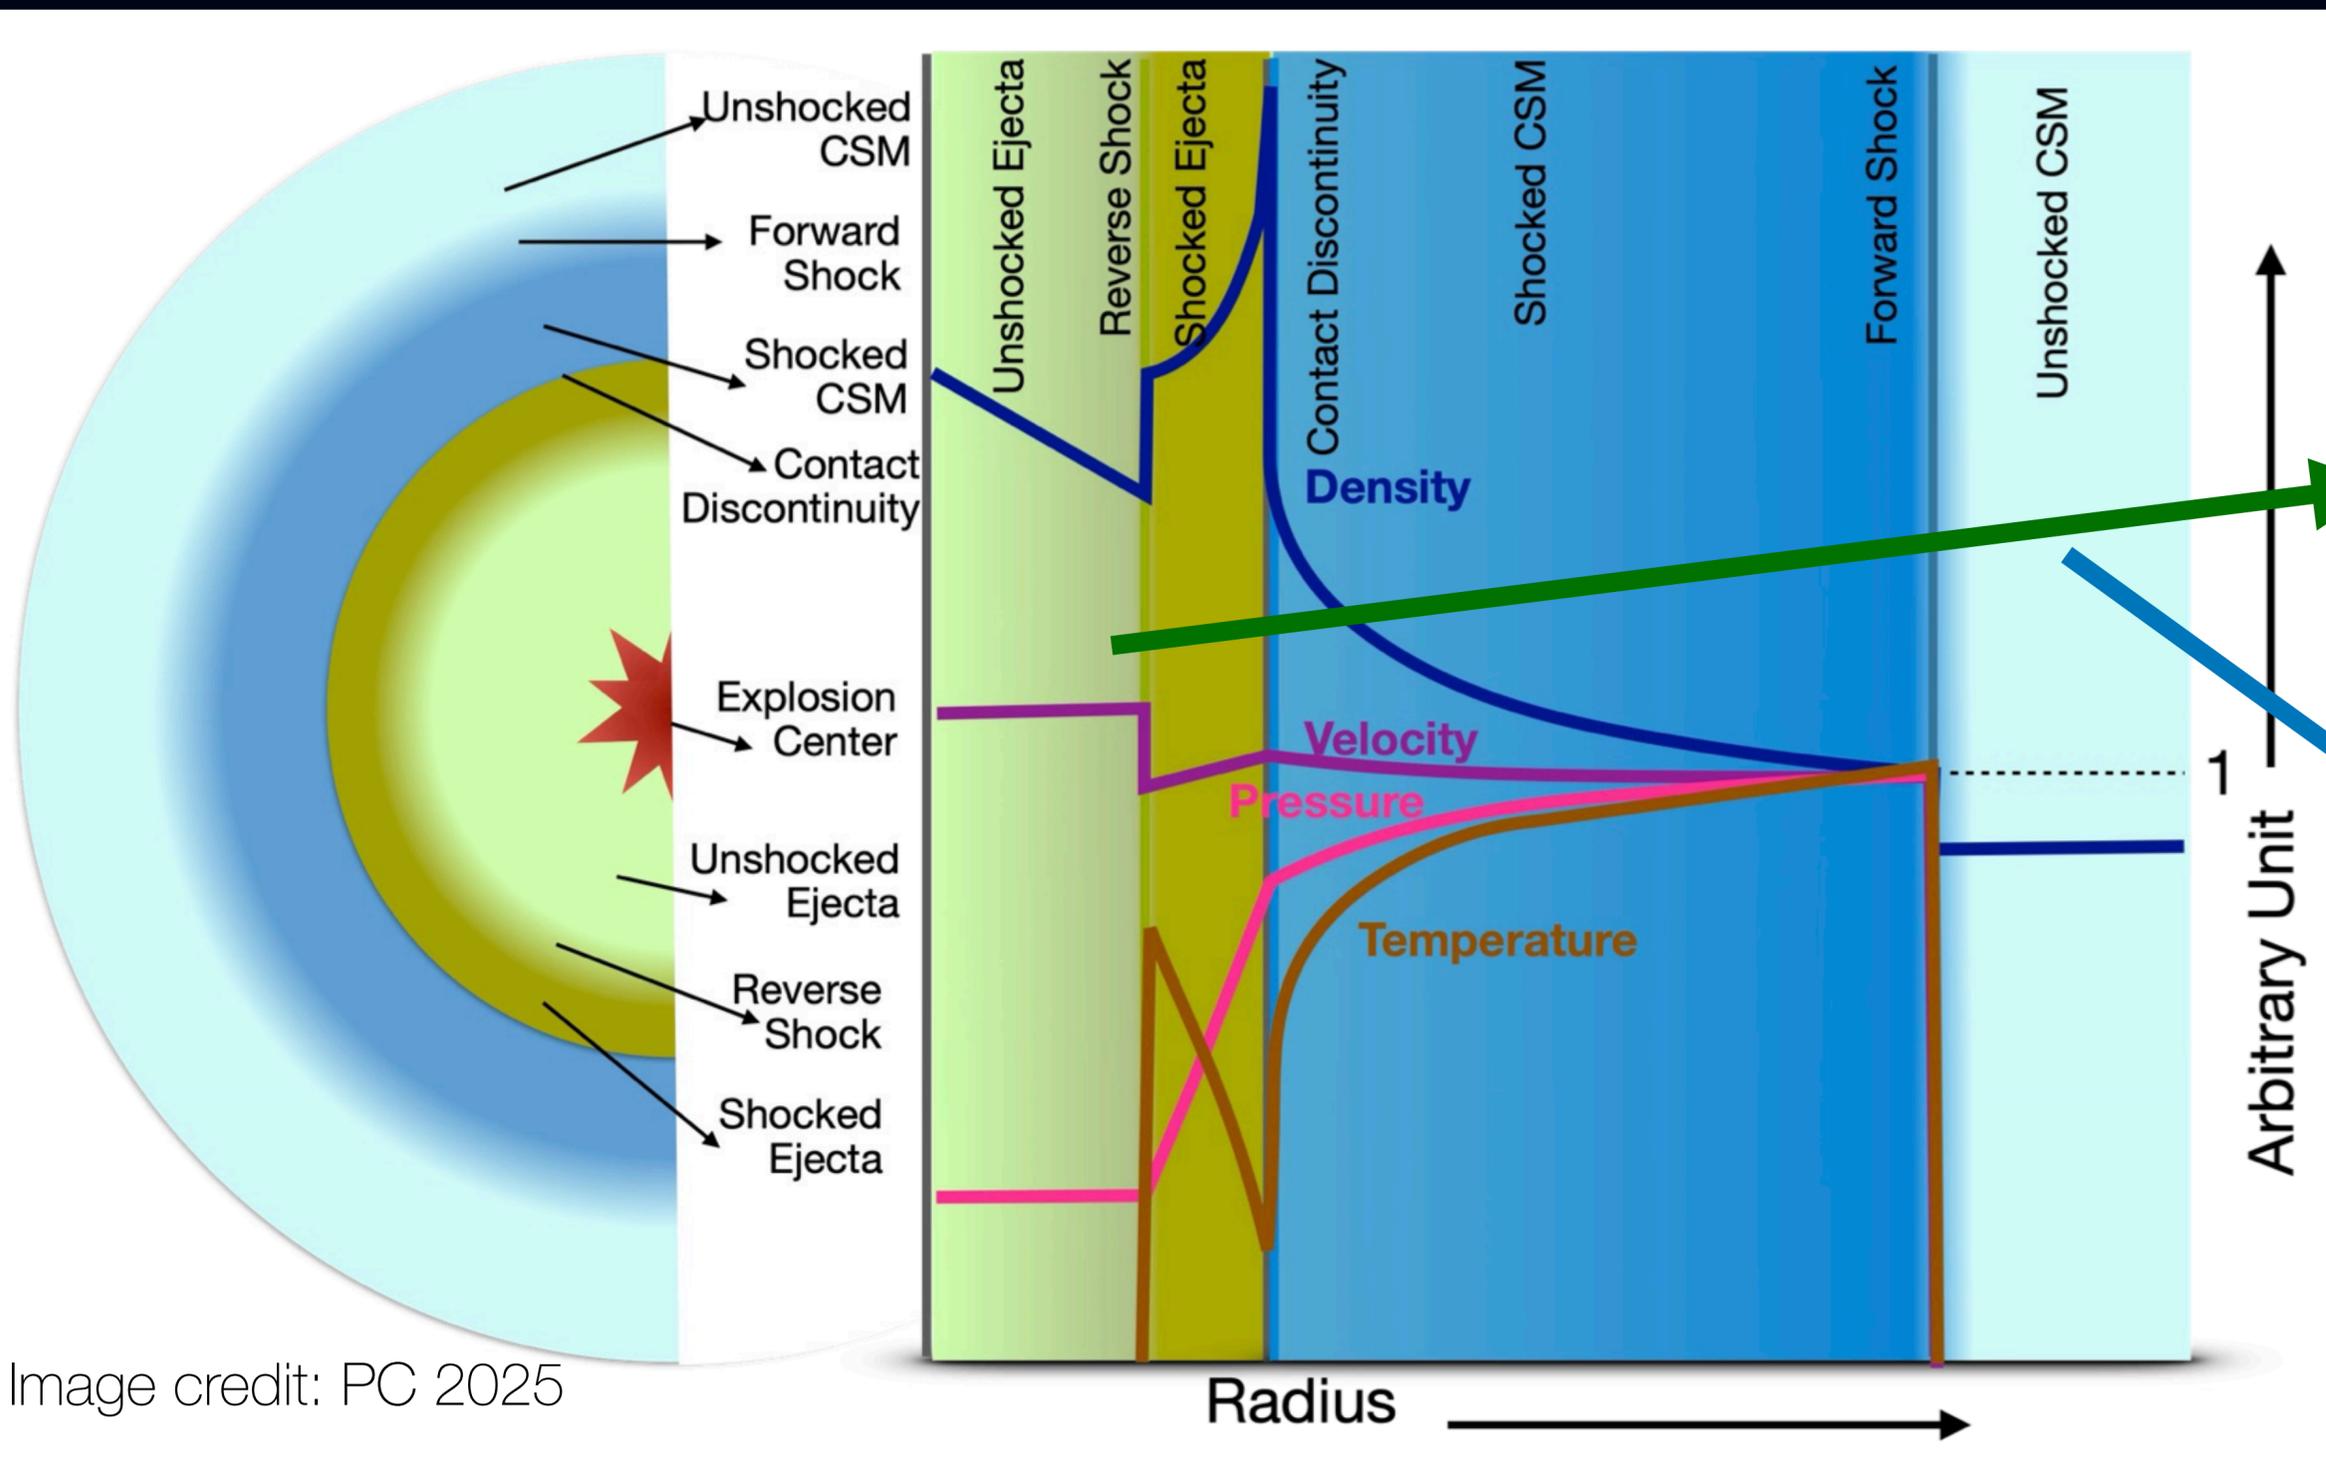

# Circumstellar Interaction - Time Machine

Fusion Stage	Time scale
Hydrogen	11 million yr
Helium fusion	2 million yr
Carbon fusion	2000 yr
Neon fusion	0.7 yr
Oxygen fusion	2.6 yr
Silicon fusion	18 d
Iron Core	~1 s

- Time Machine - Look back time = ejecta speed / wind speed
- Wind velocities and ejecta speeds different for different kinds of supernovae
  - Type IIp, ejecta speed ~10,000 km/s, wind ~10 km/s, Look back time ~1000
  - Type IIn, ejecta speed ~6000 km/s, wind ~100 km/s, look back Time ~60
  - Type Ic, ejecta speed ~30,000 km/s, wind ~1000 km/s, look back time ~30

# Circumstellar interaction- Electromagnetic emission

## Self-similar solutions Evolution of shocks

$$\rho_{ej} \propto r^{-n}, n \geq 5$$

$$\rho_{CSM} \propto r^{-2}$$

Chevalier 1982

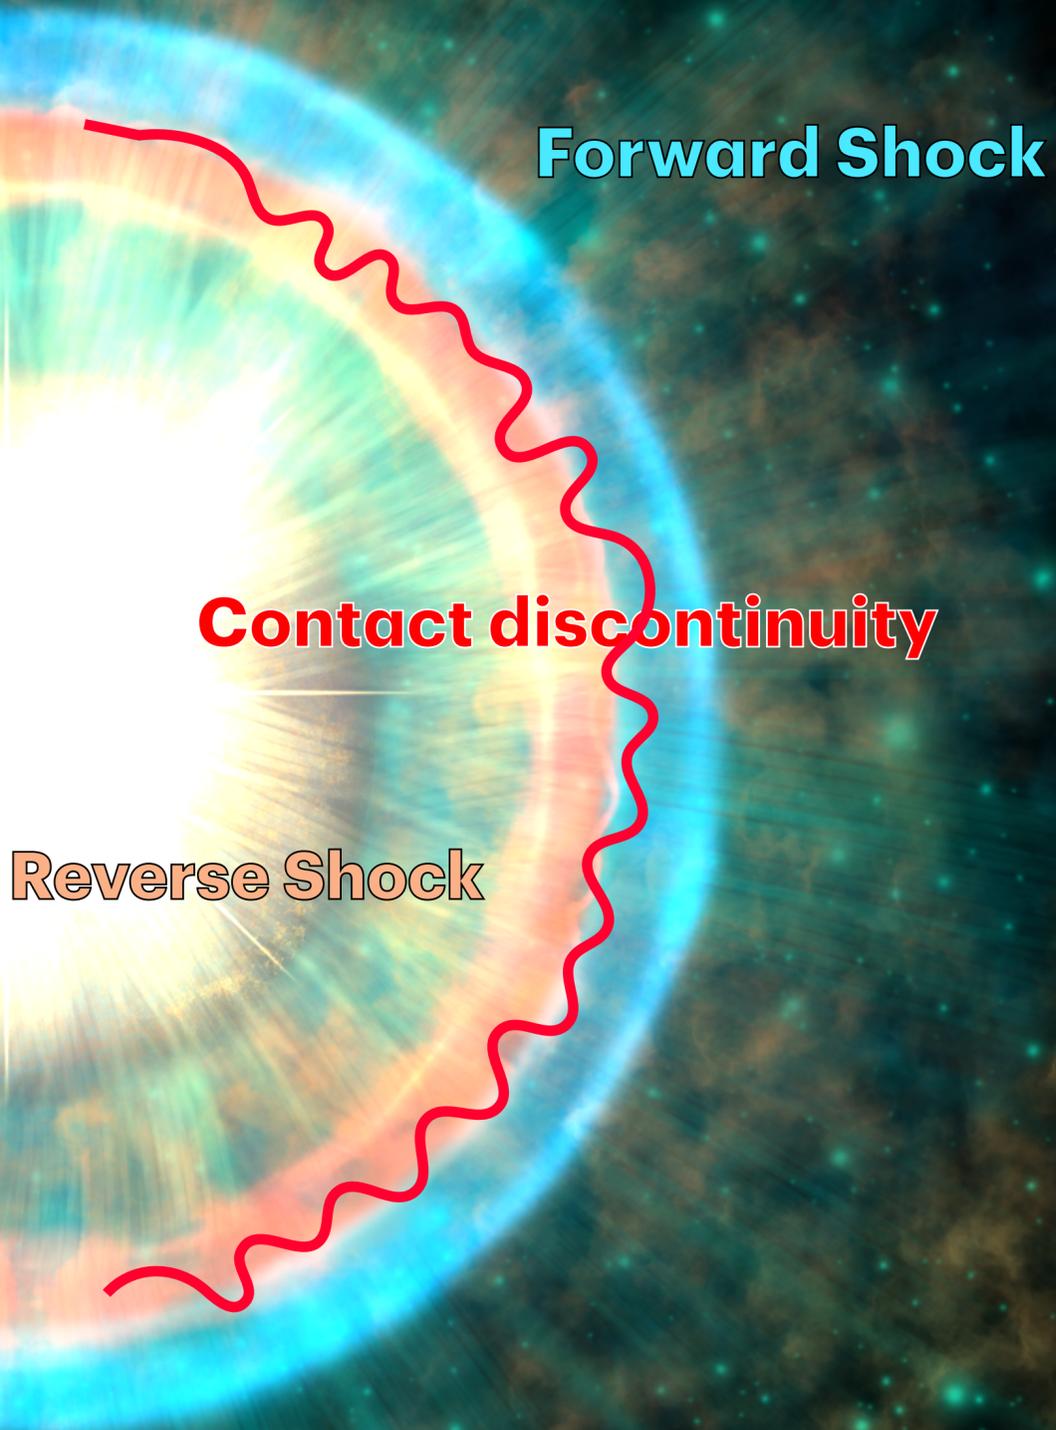

PC 2025

Image Credit: PC

Image credit: PC 2025

# CS Interaction - optical emission

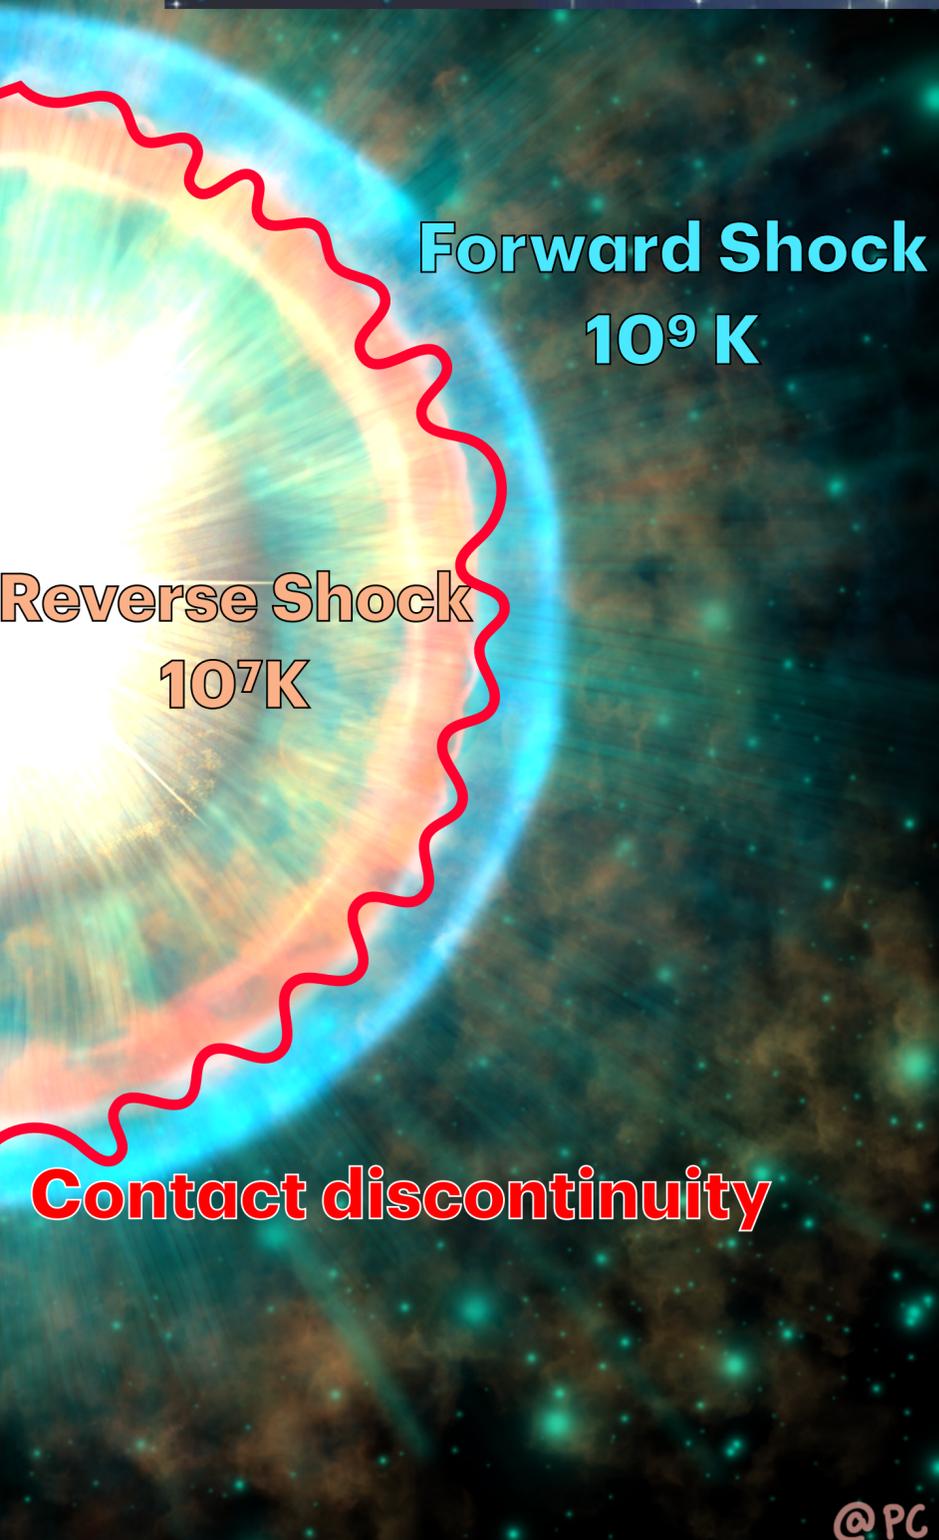

- Shock heating → ionized gas → bright lines - **strong optical emission lines**, especially hydrogen
- **Narrow emission lines** (~100 km/s): from slow, unshocked CSM photoionized by the shock radiation
- **Broad wings or broad components** (thousands of km/s): from shocked gas or electron scattering
- If the CSM density is high enough, shock energy doesn't just go into lines—it powers a **bright optical continuum**
- Reprocessing of high-energy photons into **optical bands**
  - This reprocessing is key when X-rays are weak or undetected but optical emission is strong. - SN 2006gy (Ofek+06, Chevalier, Fransson 2008)

Image Credit: PC

# X-ray emission - circumstellar interaction

- Hot forward shock -  $10^9$ K
- Reverse shock -  $10^7$ K  $n$  - ejecta density profile  $\rho^{-n}$
- RS density  $(n-3)*(n-4)/2$  x FS density ~factor of ~20
- Most dominant reverse shock  $\sim 1$  keV

$$L_i = 4\pi \int \Lambda_{\text{ff}}(T_e) n_e^2 r^2 dr \approx \Lambda_{\text{ff}}(T_i) \frac{M_i \rho_i}{(\mu_e m_H)^2}$$

- Luminosity  $\sim$  density<sup>2</sup>
- Observational evidence (Schlegel+95, Immler+2002, Dwarkadas+2012)

# CS Interaction - Radio emission

- Magnetic field amplification at the contact discontinuity
- Acceleration of electrons in the forward shock
- Non-thermal Synchrotron forward shock emission
- Radio emission from the fastest ejecta

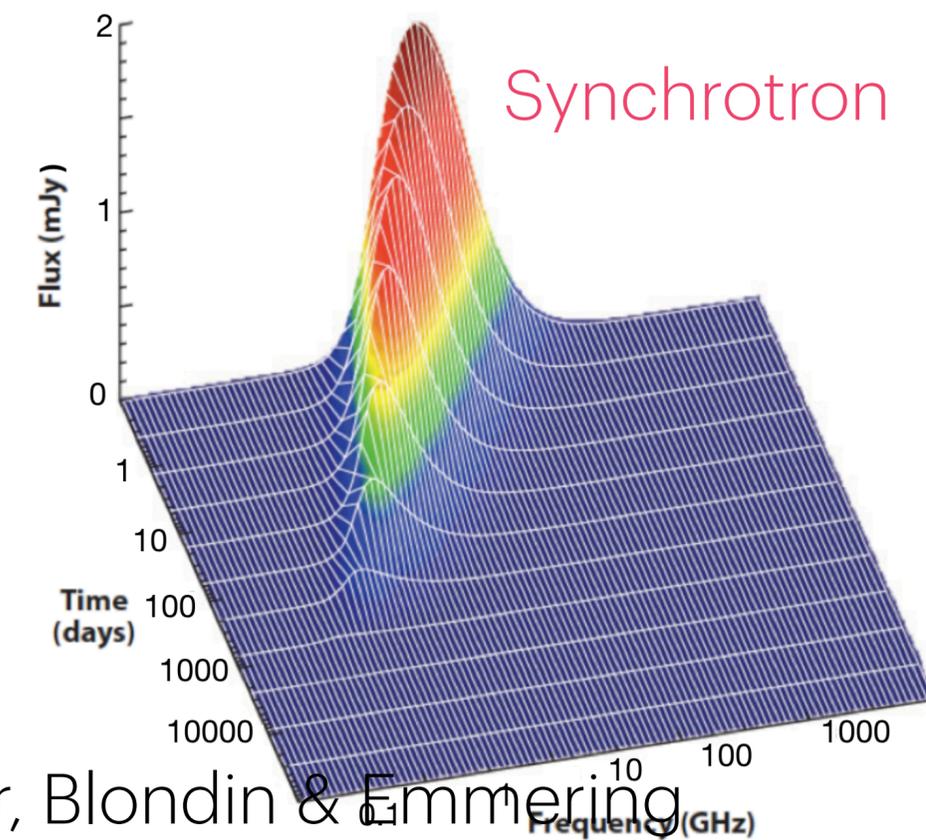

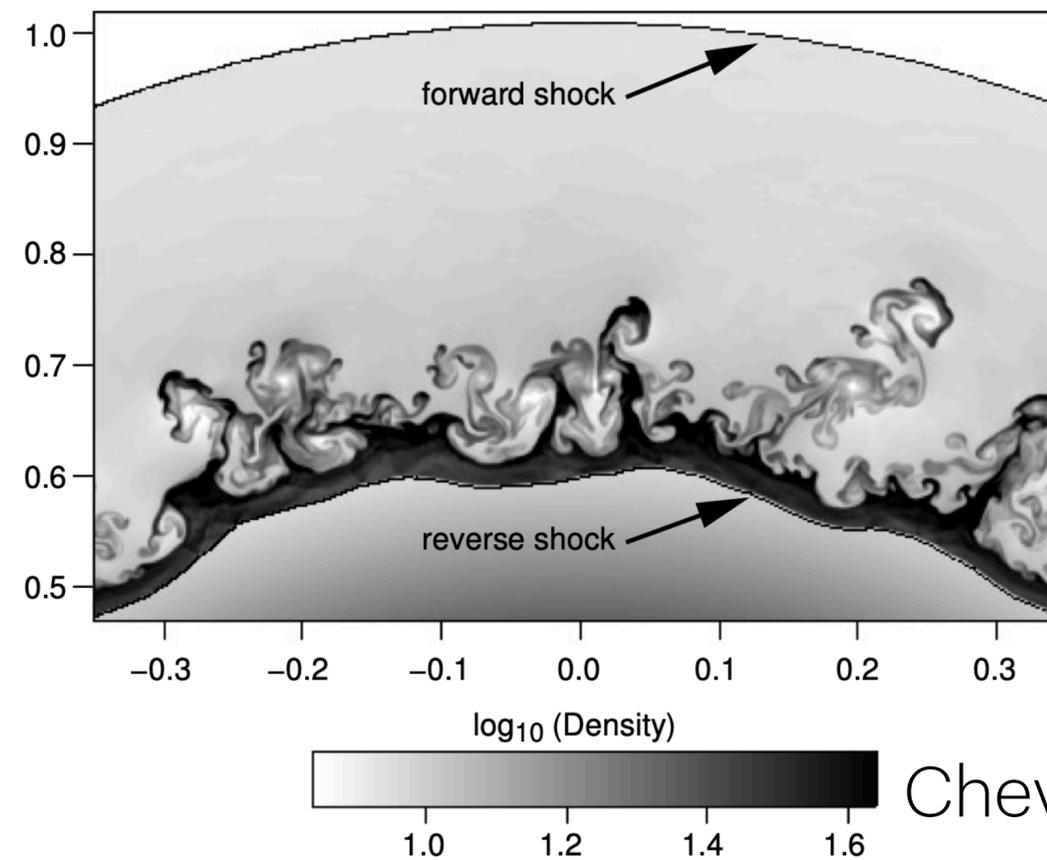

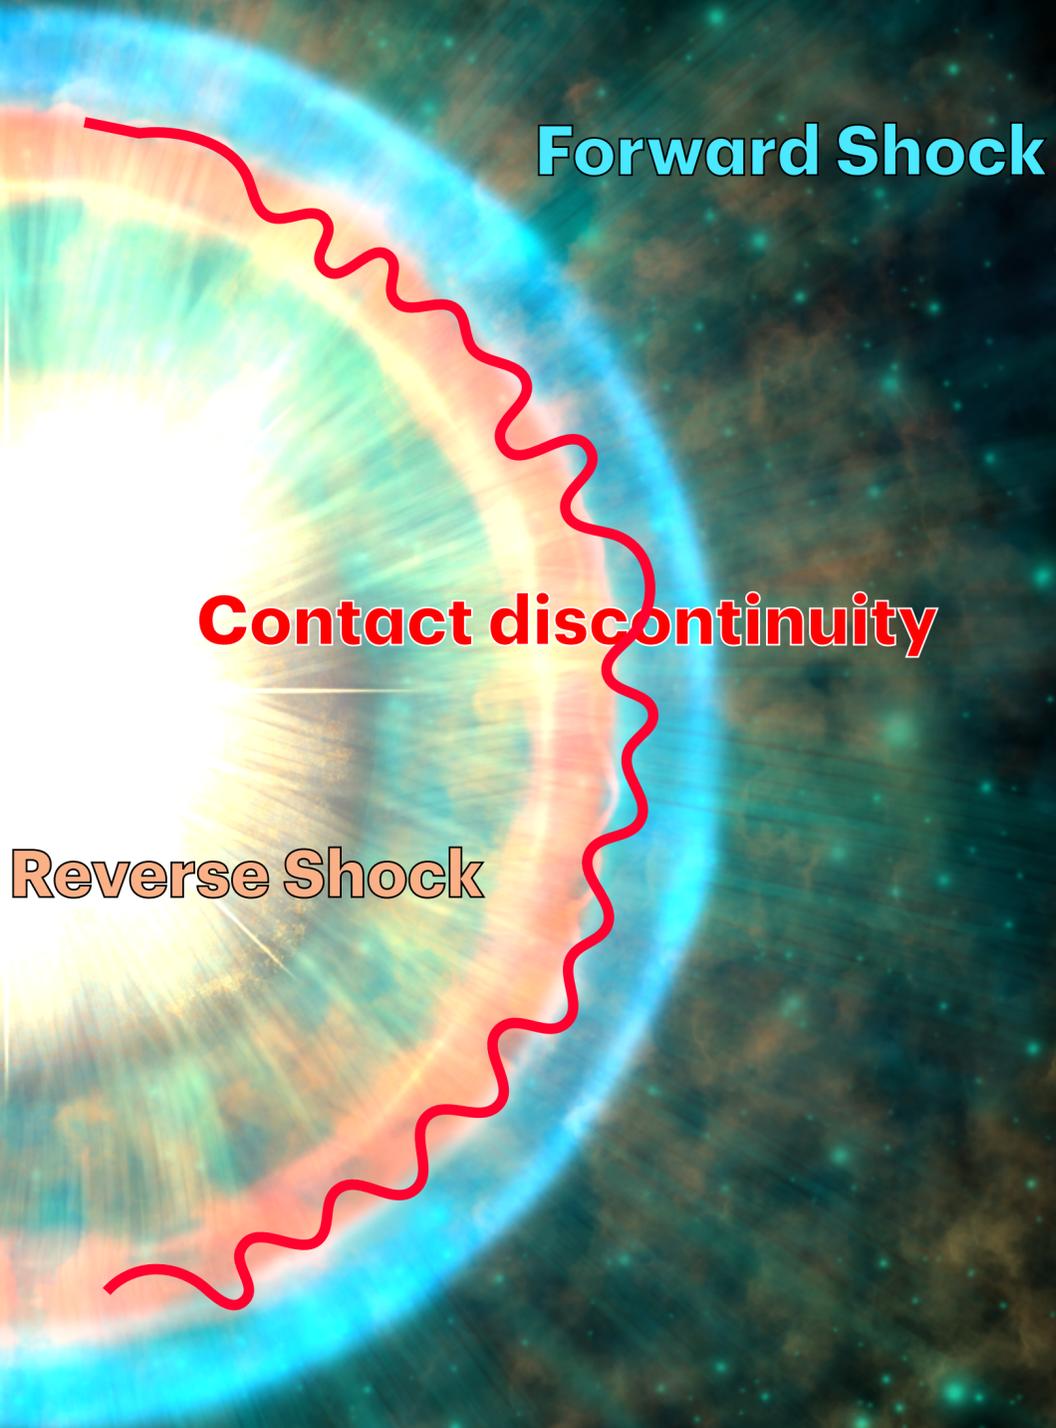

Image Credit: PC

Chevalier, Blondin & Emmering

# Circumstellar interaction - a note

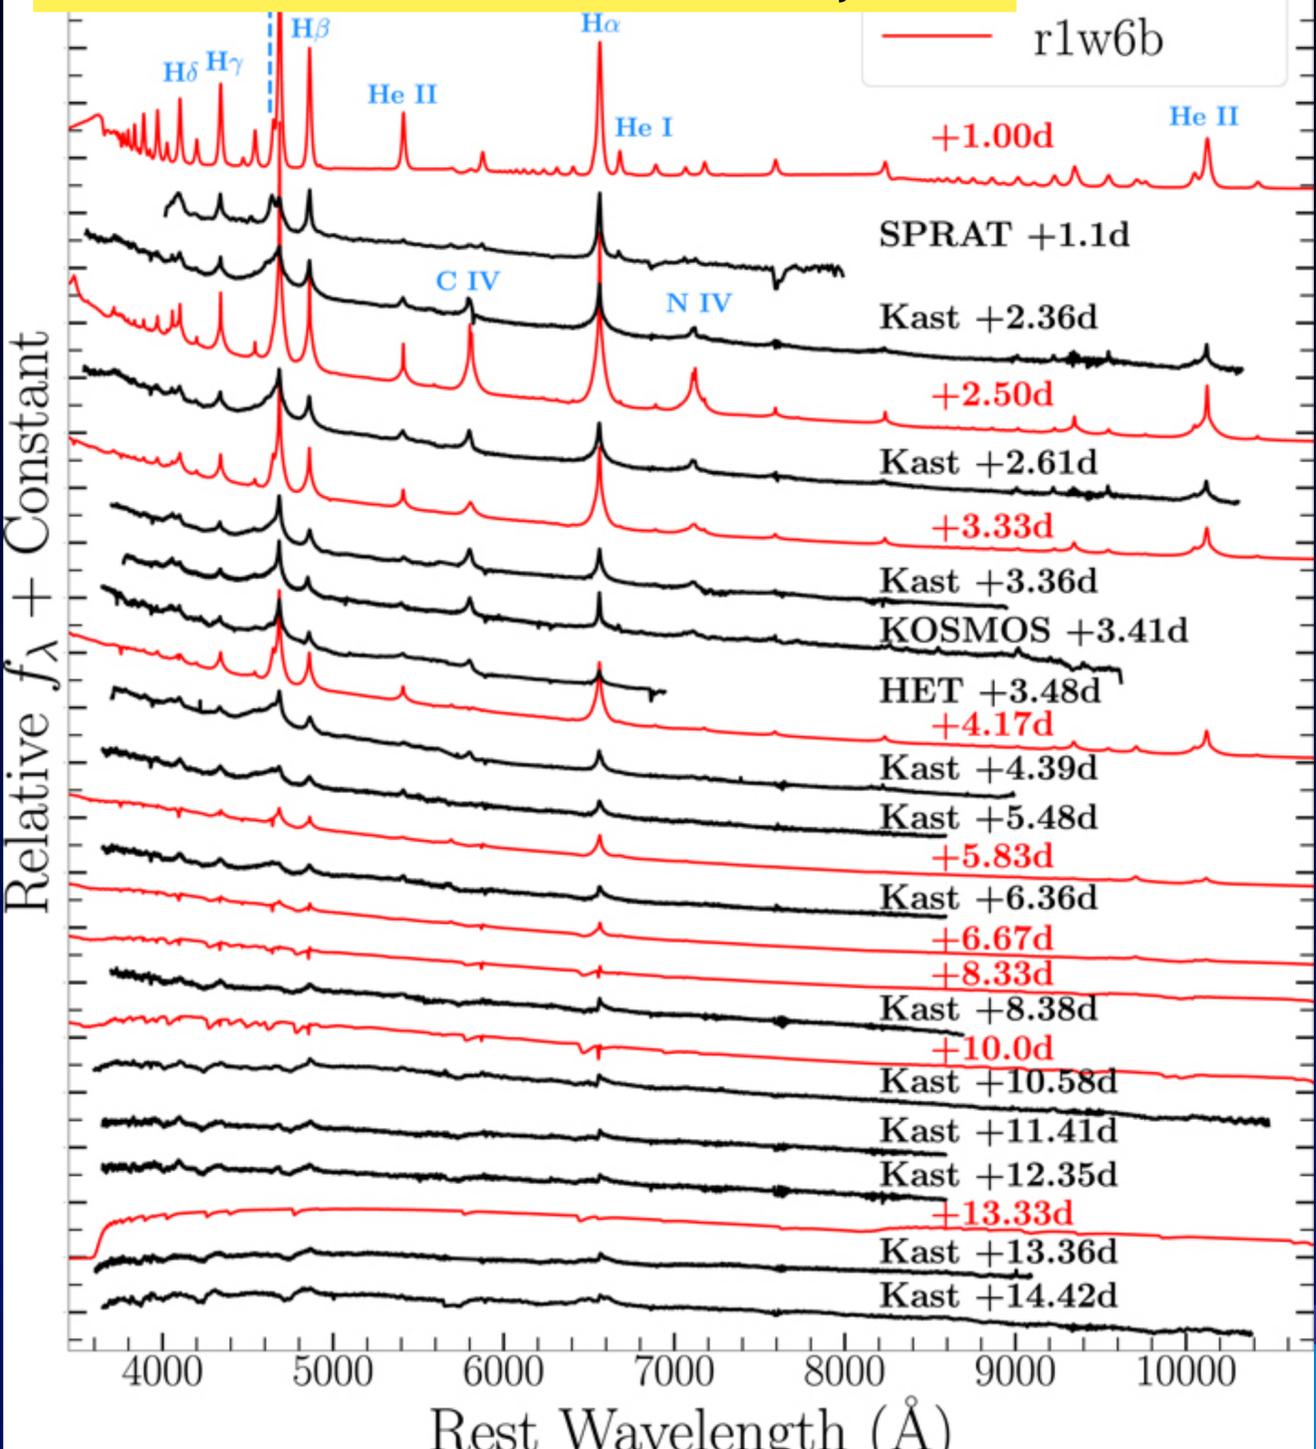

- Flash sets the boundary conditions - compact CSM
- Optical - reprocessed X-rays, thermalize UV, reshape optical spectra, mixed with radioactivity
- X-ray - absorption, reprocessing, inverse-Compton, radiative vs adiabatic physics
- Radio - whether the shocks are truly coupling to the circumstellar medium. **Most direct and least ambiguous tracer of circumstellar interaction**

# CSM and Circumstellar interaction - a note

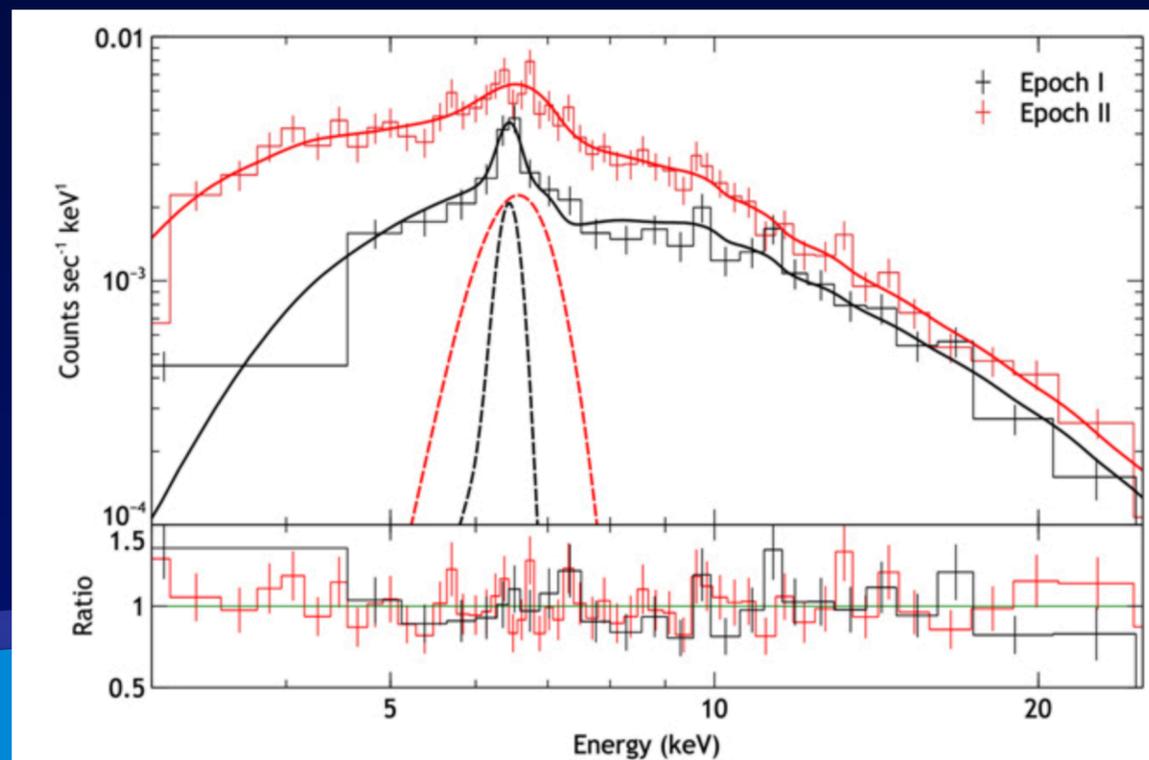

- Explosion → flash ionization → CS interaction onset → long-term interaction  
 $10^{14}$ - $10^{15}$ cm       $10^{15}$ - $10^{16}$ cm       $10^{16}$ - $10^{18}$ cm
- Flash ionization only  
→ small amount of nearby CSM, quickly exhausted
- Flash ionization + strong CS interaction  
→ dense, radially extended CSM
- No flash ionization, but late CS interaction  
→ inner region relatively clean, dense CSM farther out (decades–centuries old mass loss)

# SN 2023ixf - flash features as well as X-rays

- Jacobson-Galán+23, Teja+23 SN 2023ixf

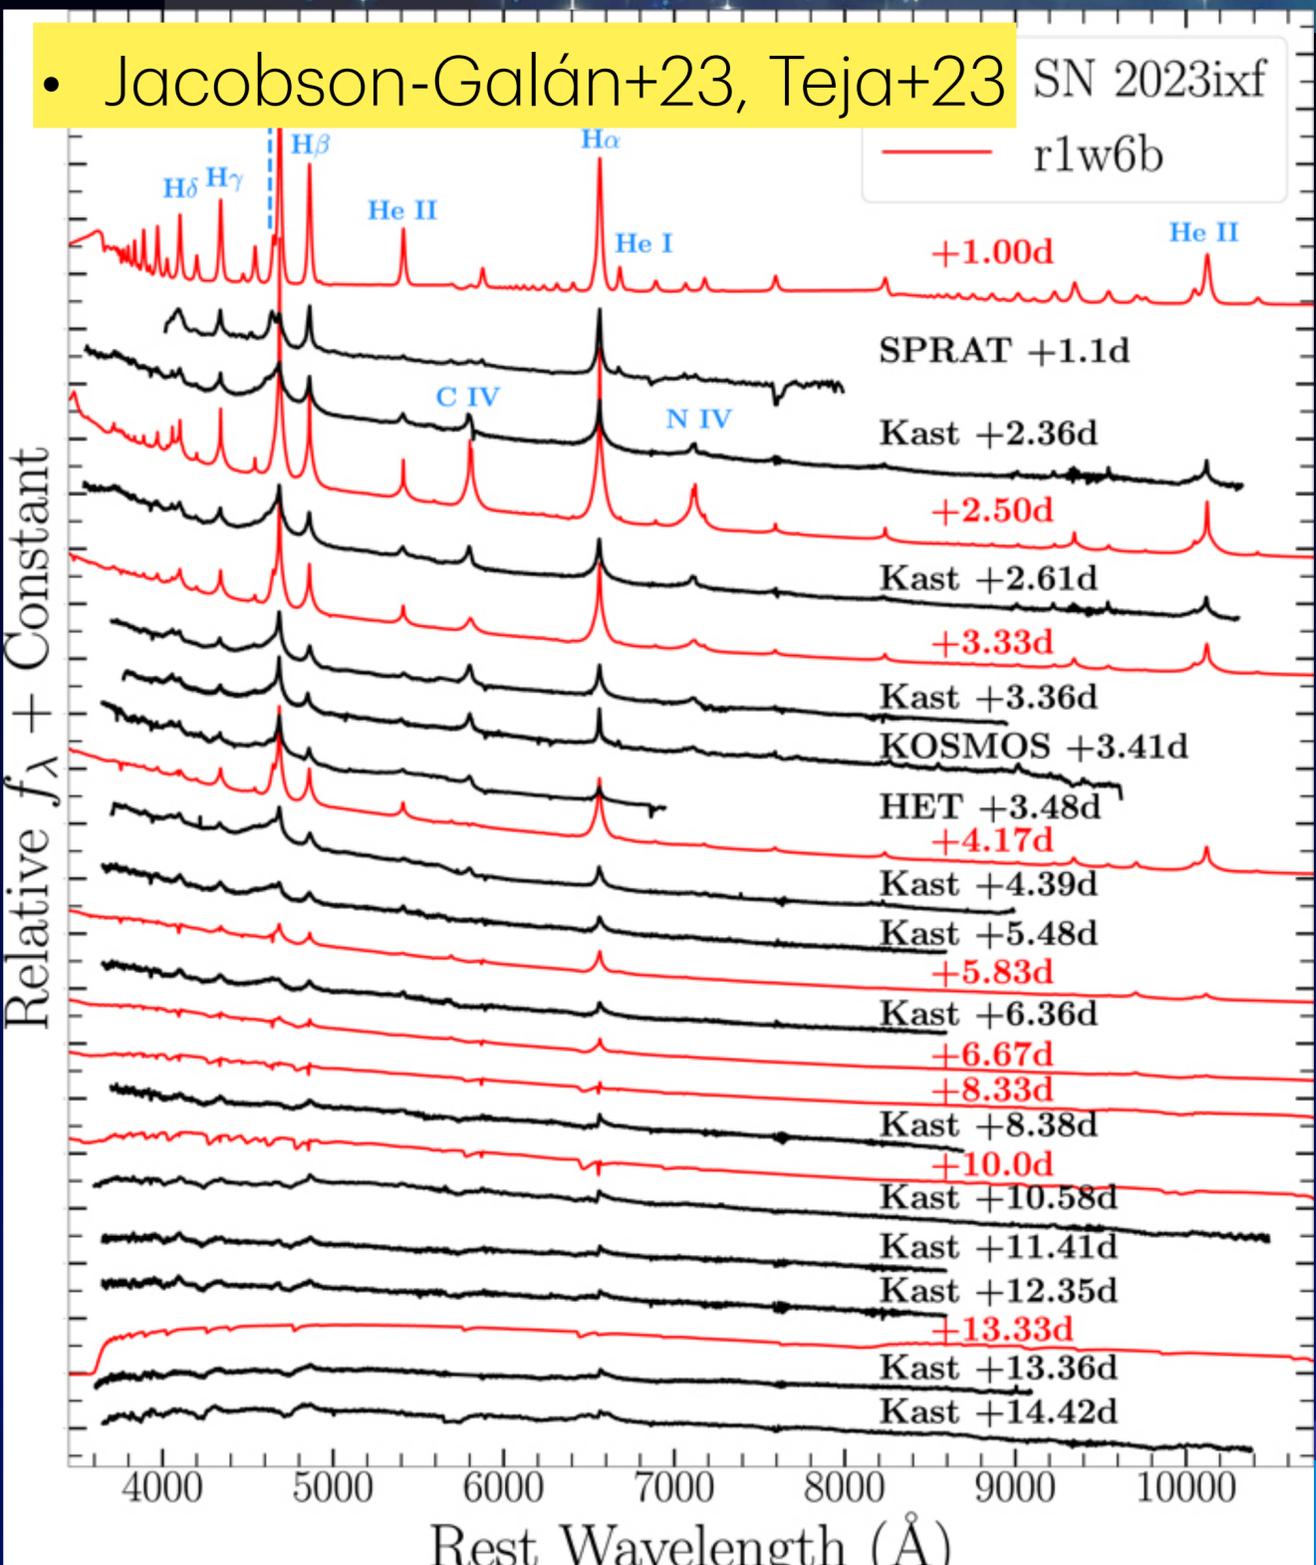

- Flash ionization - probes optically thin inner CSM, X-rays generally absorbed
- SN 2023ixf - flash ionization (Jacobson-Galán+23, Teja+23)
- X-ray detection on day 4 - Moderate CSM (Grefenstette+23)

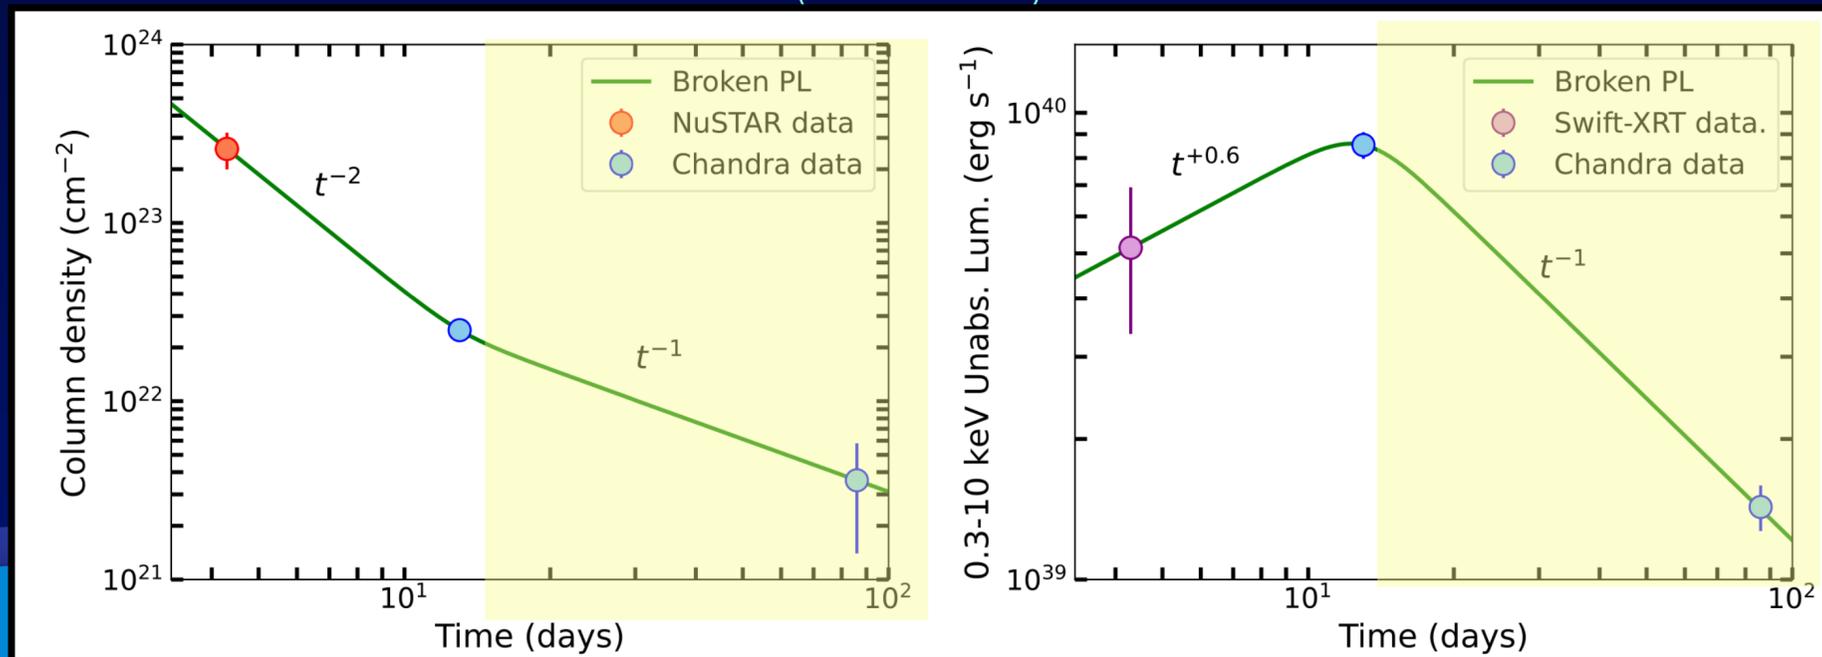

# SN 2023ixf - flash features as well as X-rays

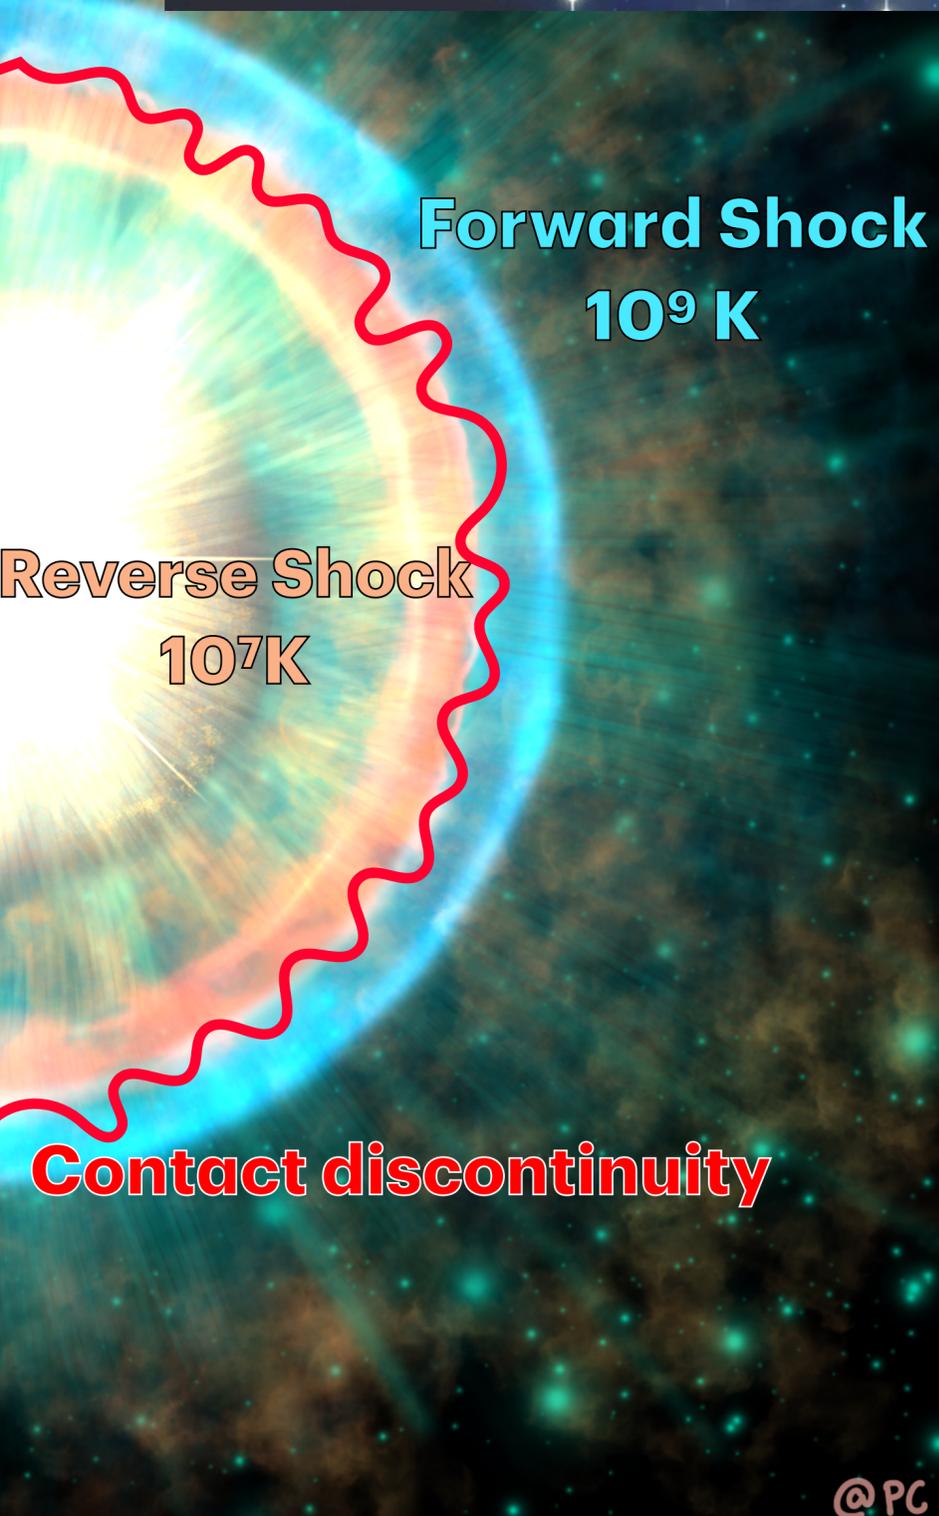

- Jacobson-Galán+23, Teja+23 SN 2023ixf

- Flash ionization - probes optically thin inner CSM, X-rays generally absorbed
- SN 2023ixf - flash ionization (Jacobson-Galán+23, Teja+23)
- X-ray detection on day 4 - Moderate CSM (Grefenstette+23)
- Late time data consistent with constant mass-loss rate and standard  $1/R^2$  CSM (PC+24)

# CS interaction in X-rays

- Hot forward shock -  $10^9$ K
- Reverse shock -  $10^7$ K  $n$  - ejecta density profile  $\rho^{-n}$
- RS density  $(n-3)*(n-4)/2$  x FS density ~factor of ~20
- Most dominant reverse shock  $\sim 1$  keV

$$L_i = 4\pi \int \Lambda_{\text{ff}}(T_e) n_e^2 r^2 dr \approx \Lambda_{\text{ff}}(T_i) \frac{M_i \rho_i}{(\mu_e m_H)^2}$$

- Luminosity  $\sim$  density<sup>2</sup>
- Observational evidence (Schlegel+95, Immler+2002, Dwarkadas+2012)

# X-ray emission - circumstellar interaction

Reverse shock radiative

- Cooling time ~  
Chevalier, Fransson 2017

$$t_{\text{cool}} \sim \frac{605}{(n-3)(n-4)(n-2)^{3.34}} \left( \frac{V_{\text{ej}}}{10^4 \text{ km s}^{-1}} \right)^{5.34} \left( \frac{\dot{M}_{-5}}{u_{w1}} \right)^{-1} \left( \frac{t}{\text{days}} \right)^2 \text{ days,}$$

- Radiative reverse shock

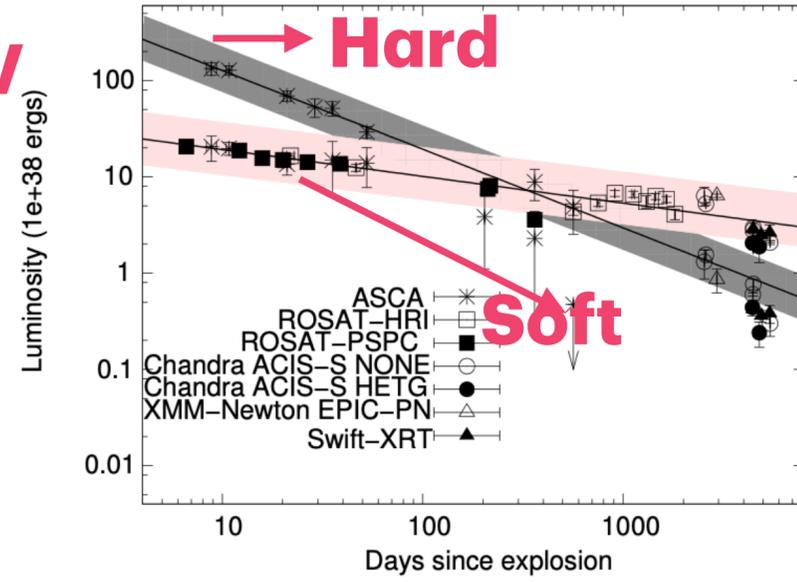

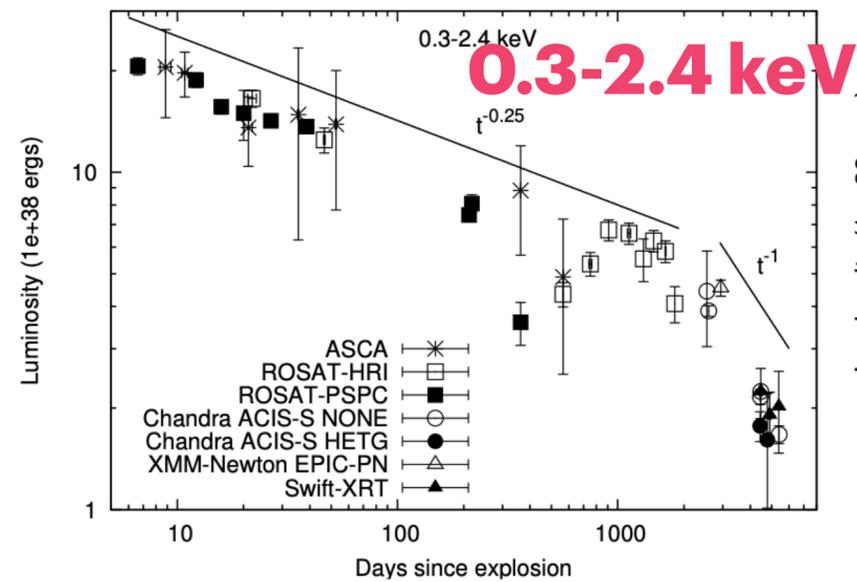

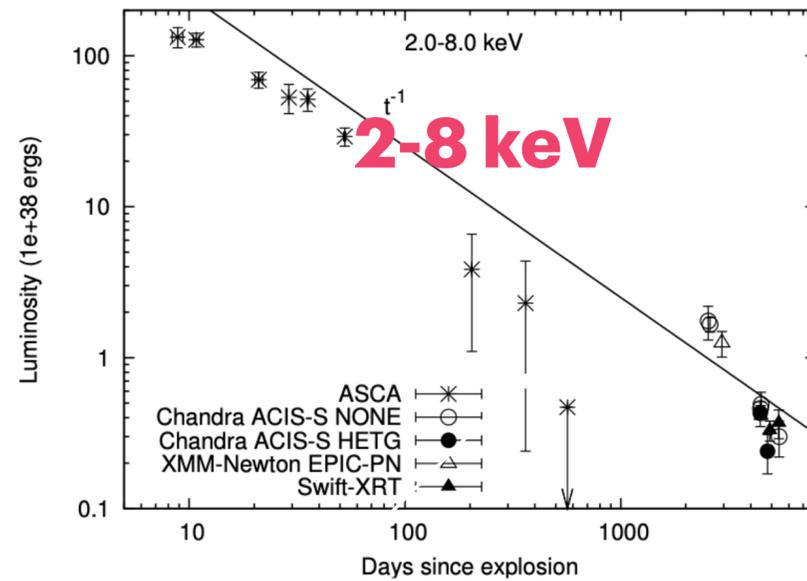

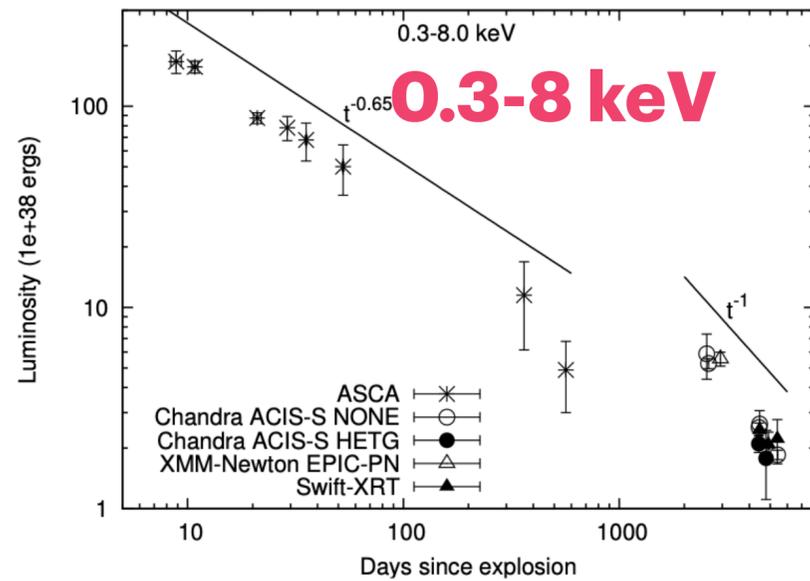

$$L_{\text{rev}} = 4\pi R_s^2 \frac{1}{2} \rho_{\text{ej}} v_{\text{rev}}^3$$

Luminosity ~ density

- SN 1993J - Radiative Reverse Shock - Fransson+96

# X-ray emission - circumstellar interaction

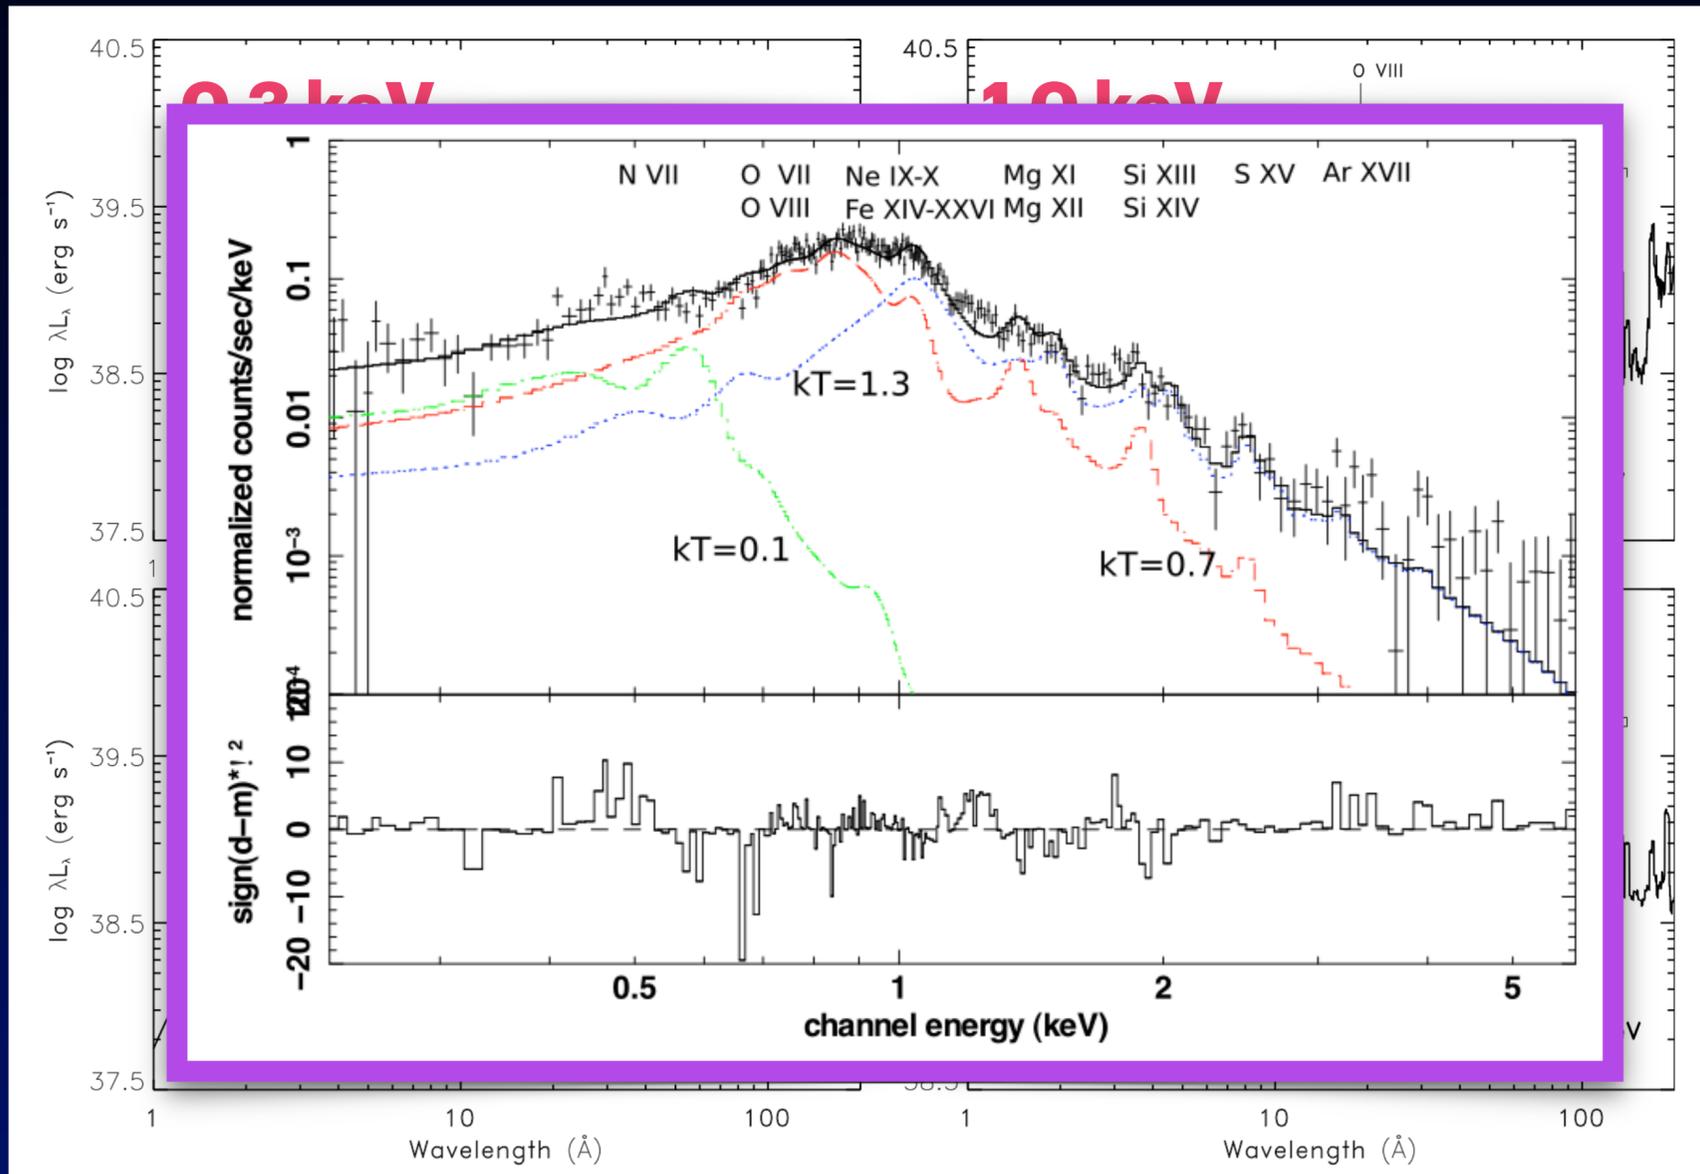

## Reverse shock radiative - SN 1993J

- Reverse shock radiative up to  $\sim 5$  years after explosion and adiabatic after that (PC+2009)
- Consistent with SN 1993J modeling (Nomoto & Suzuki)

# X-ray emission - circumstellar interaction

Reverse shock radiative - SN 1993J

- Reverse shock radiative up to  $\sim 5$  years after explosion and adiabatic after that (PC+2009)
- Consistent with SN 1993J modeling (Nomoto & Suzuki)
- Single temperature model invalid (Nymark et al. 2006)
- Demonstrated multi-temperature model in SN 1993J (Nymark, PC, Fransson 2006)

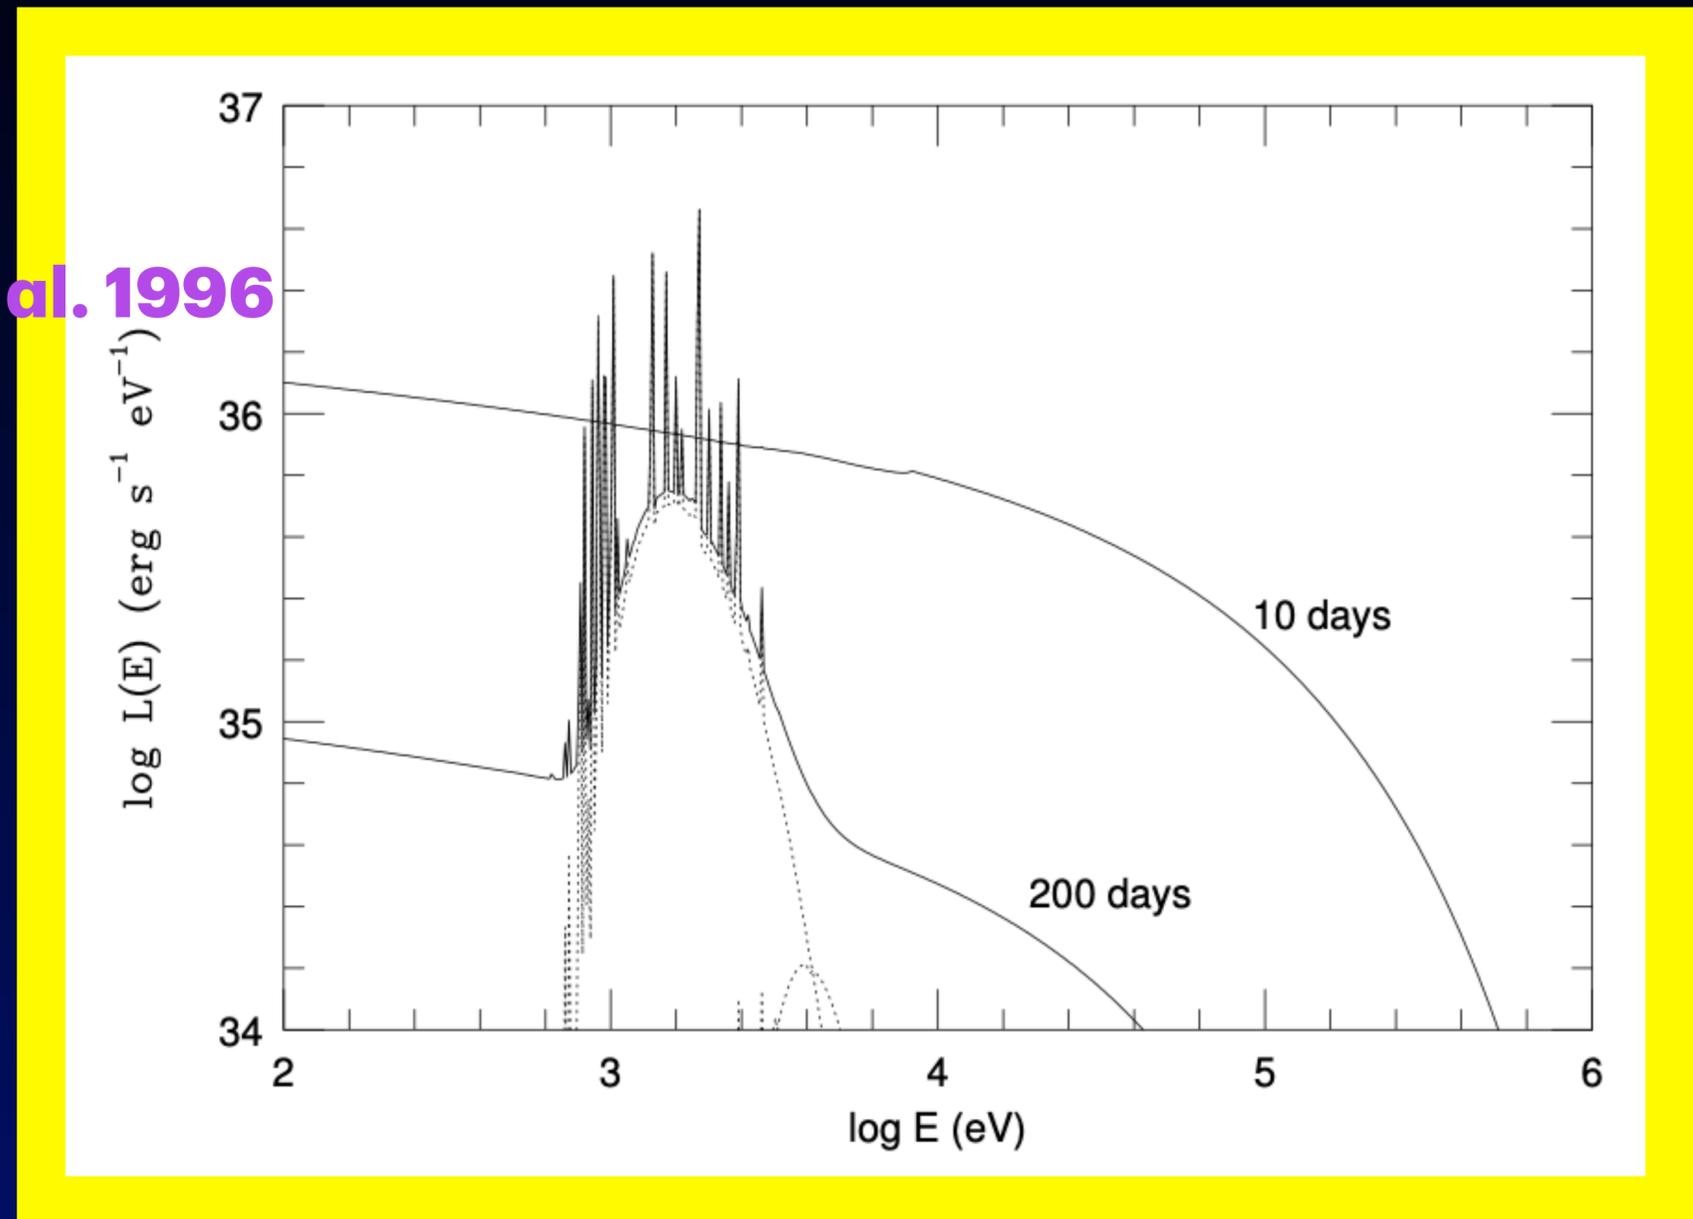

Nymark et al. 2006, Nymark, PC, Fransson+2009

# X-ray emission - circumstellar interaction

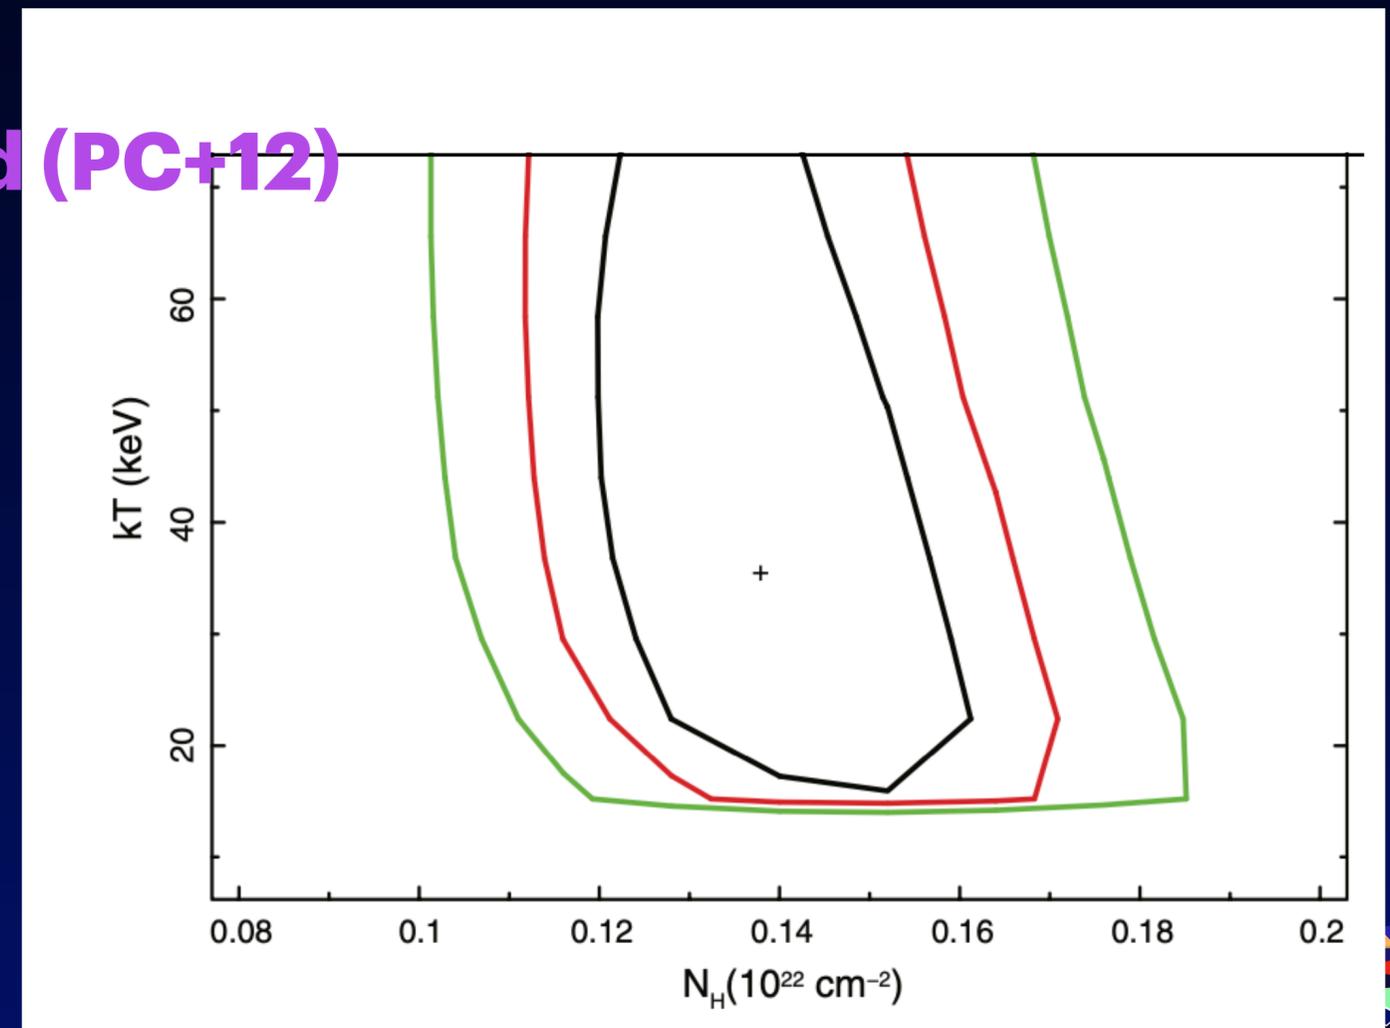

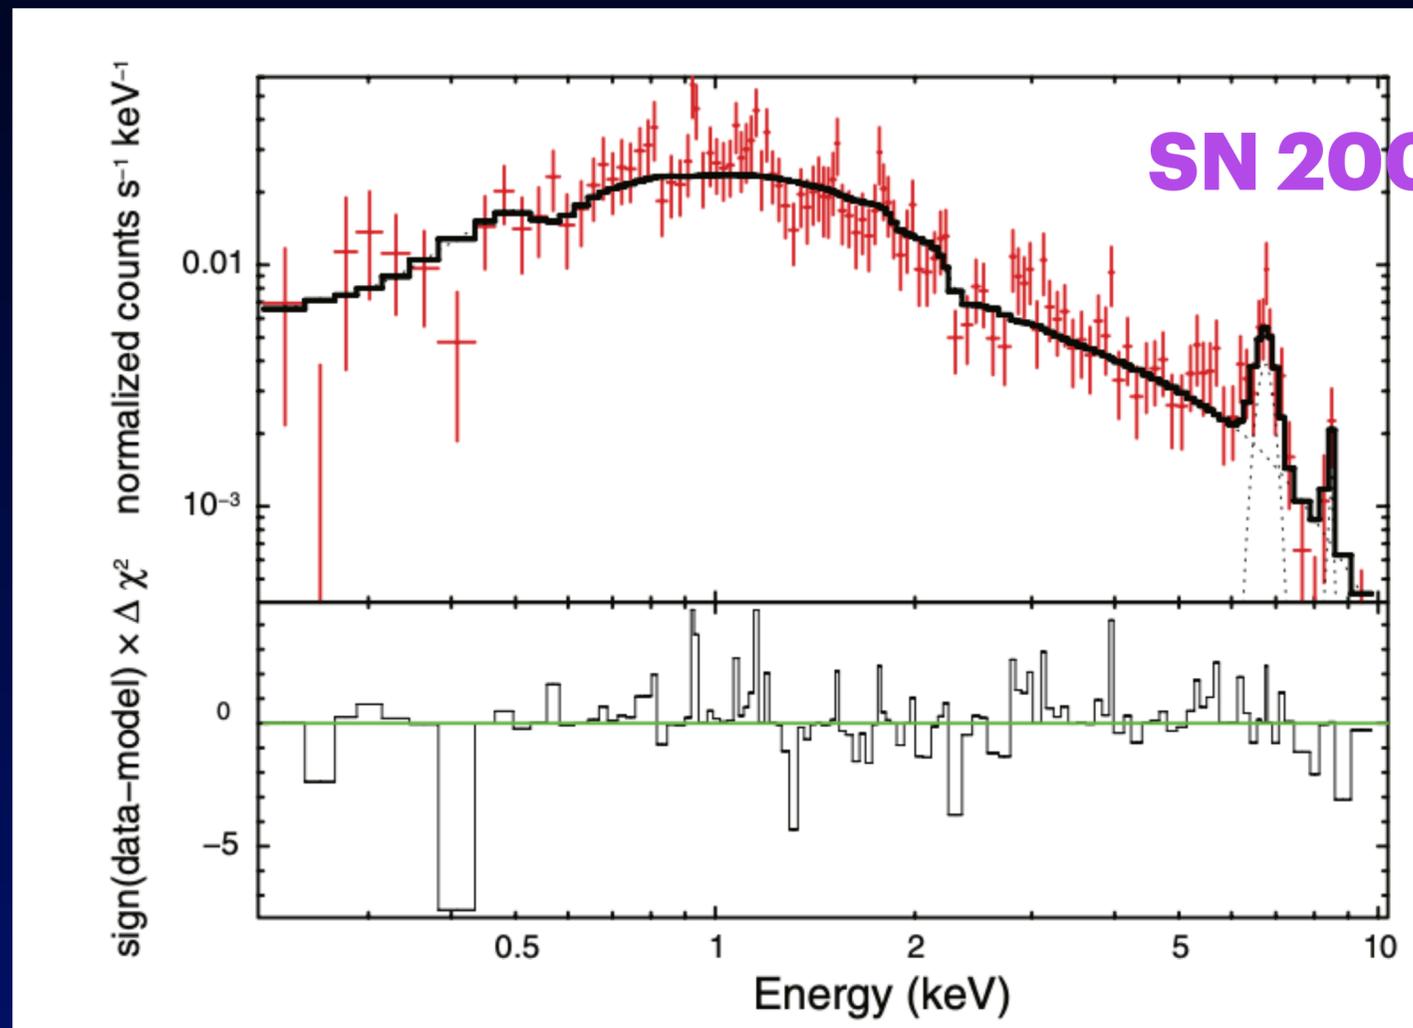

Fransson et al. 1996

# X-ray emission - circumstellar interaction

Hard X-rays

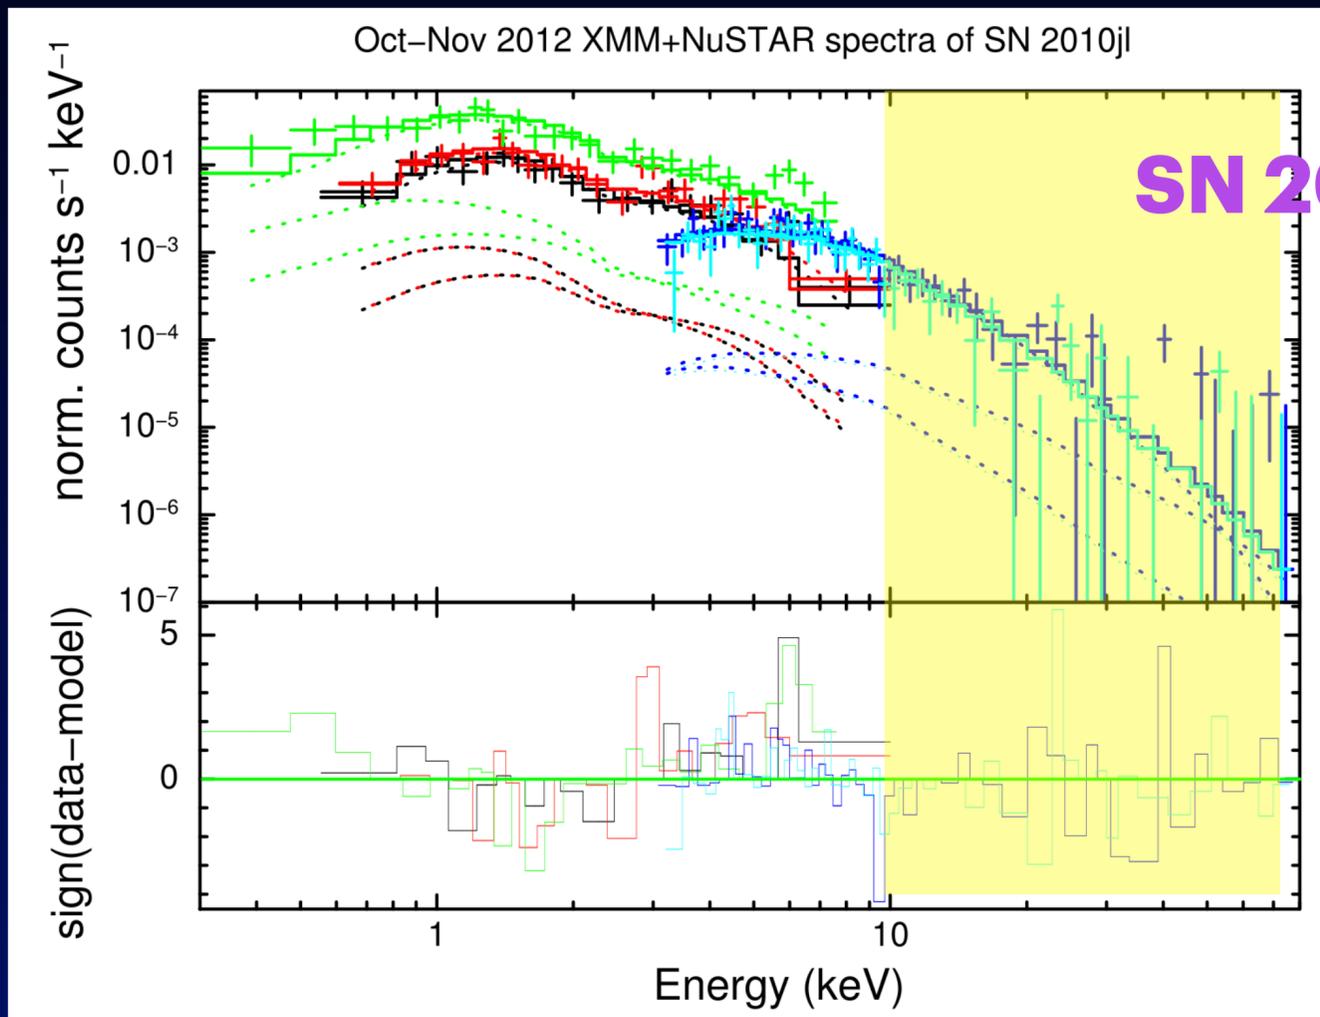

- Chandra/XMM energy range 0.3-10 keV

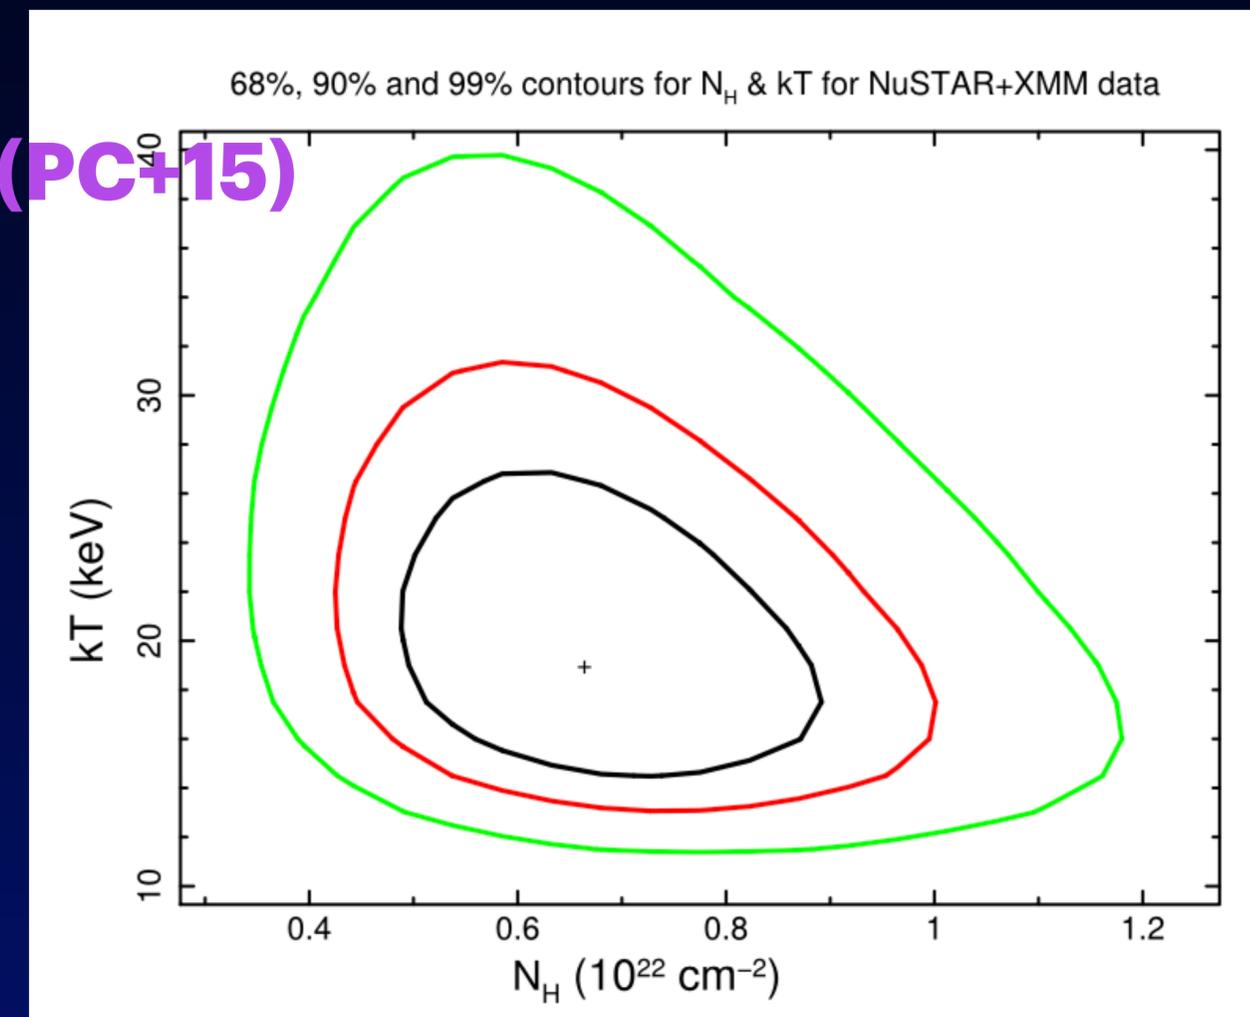

# X-ray emission - circumstellar interaction

Hard X-rays

- NuSTAR revolutionary

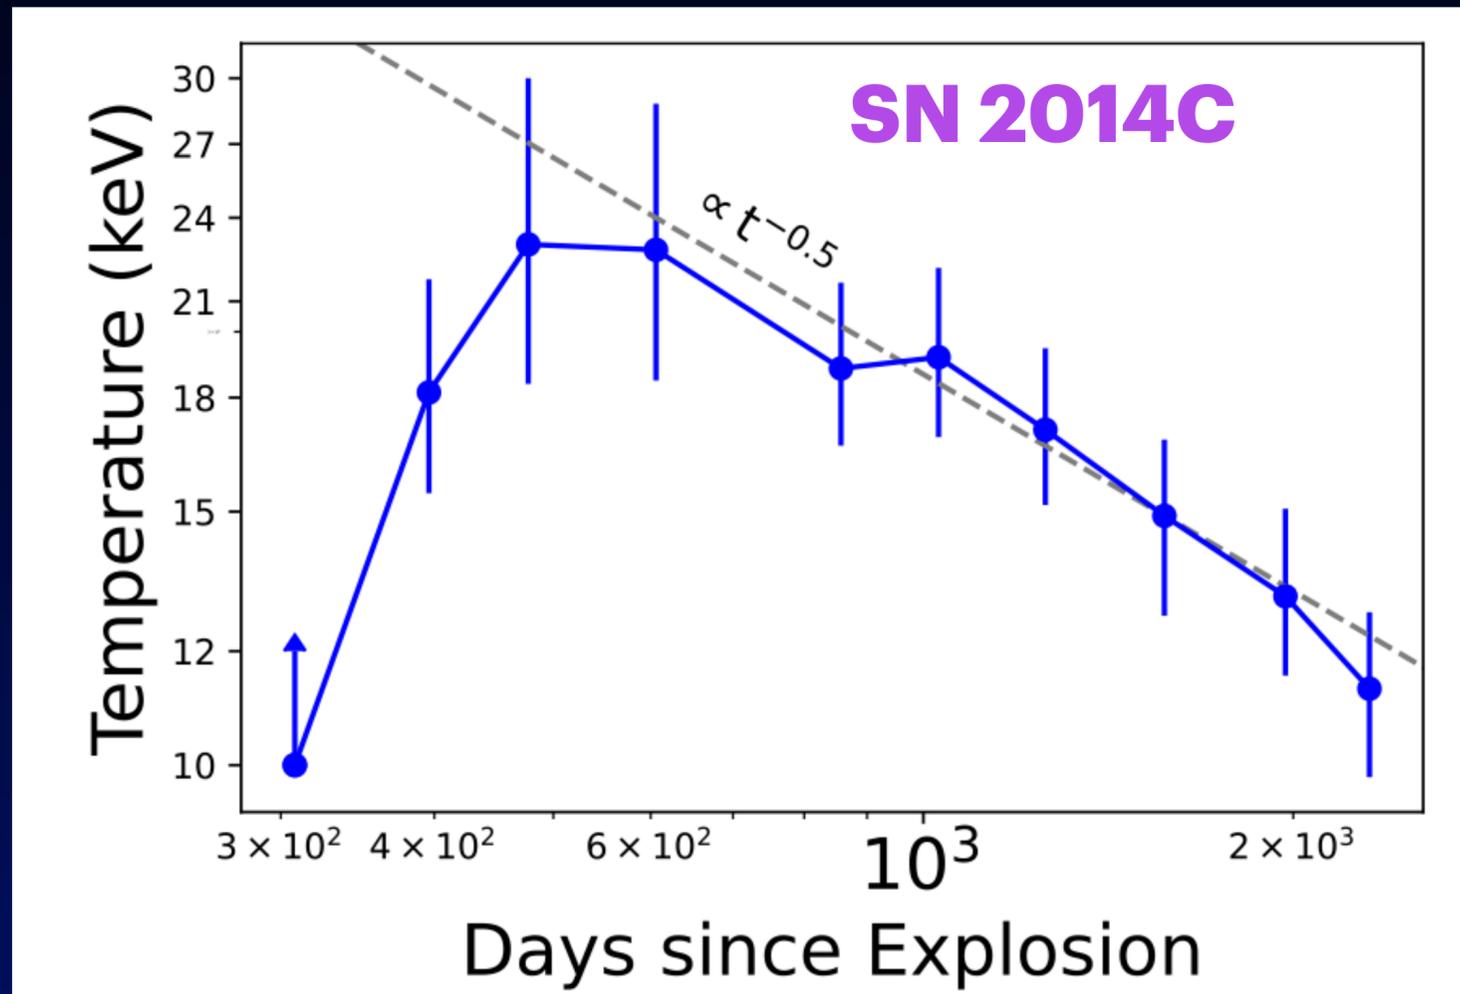

SN 2010jl (PC+15)

# X-ray emission - circumstellar interaction

Hard X-rays

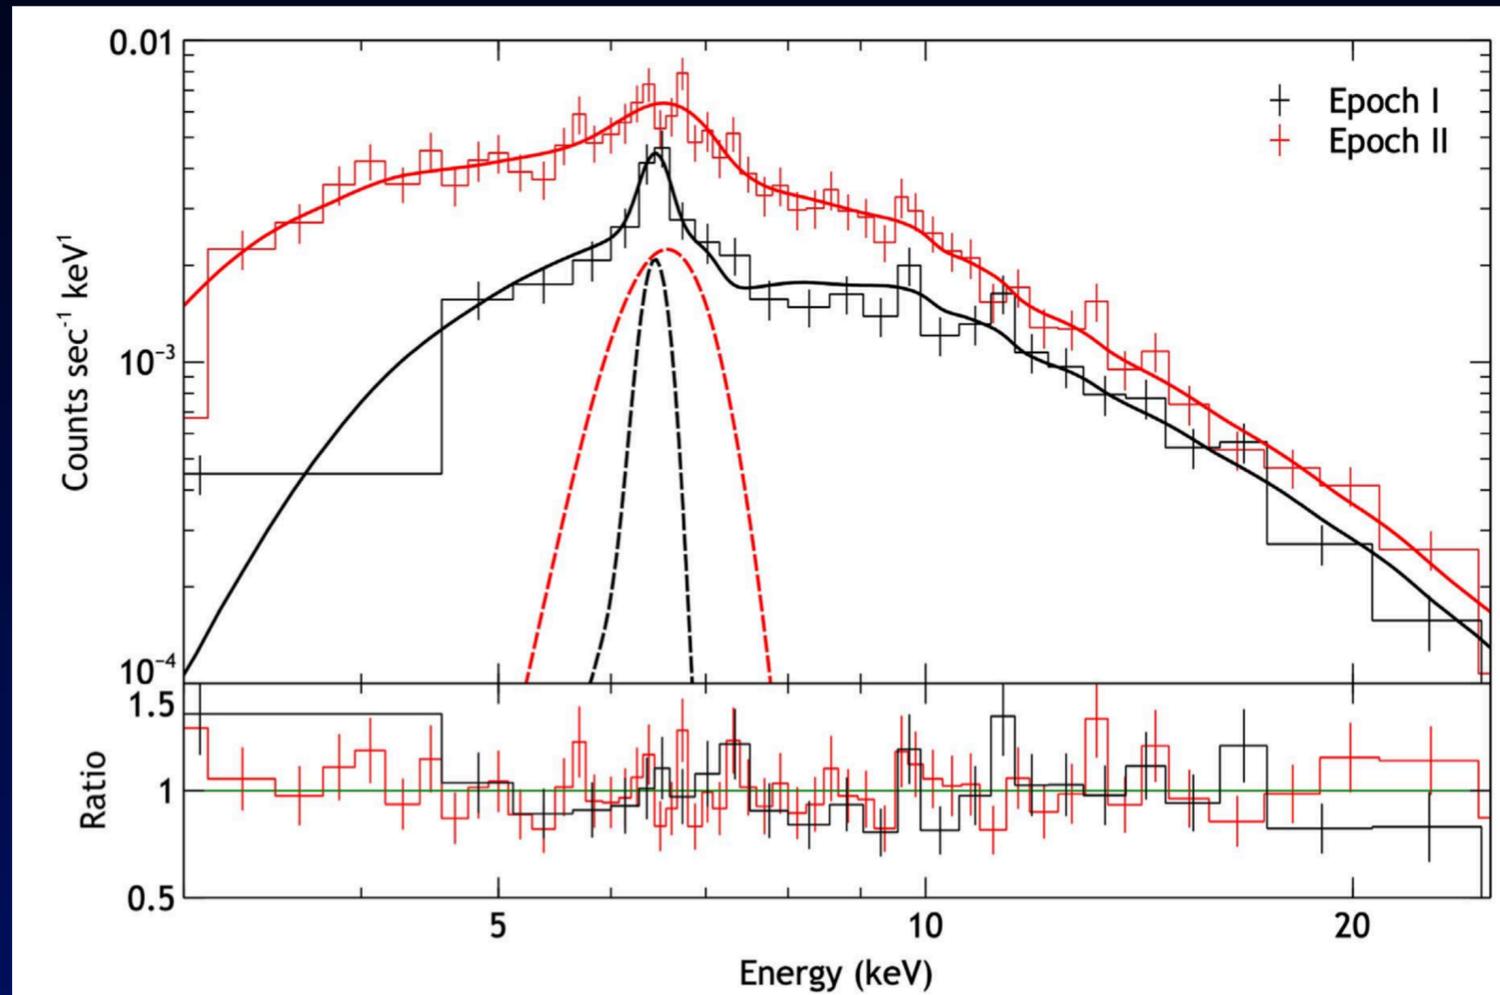

- NuSTAR revolutionary
- Temperature evolution of SN 2014C (Brethauer+22)

- Brethauer+22

# X-ray emission - circumstellar interaction

Hard X-rays

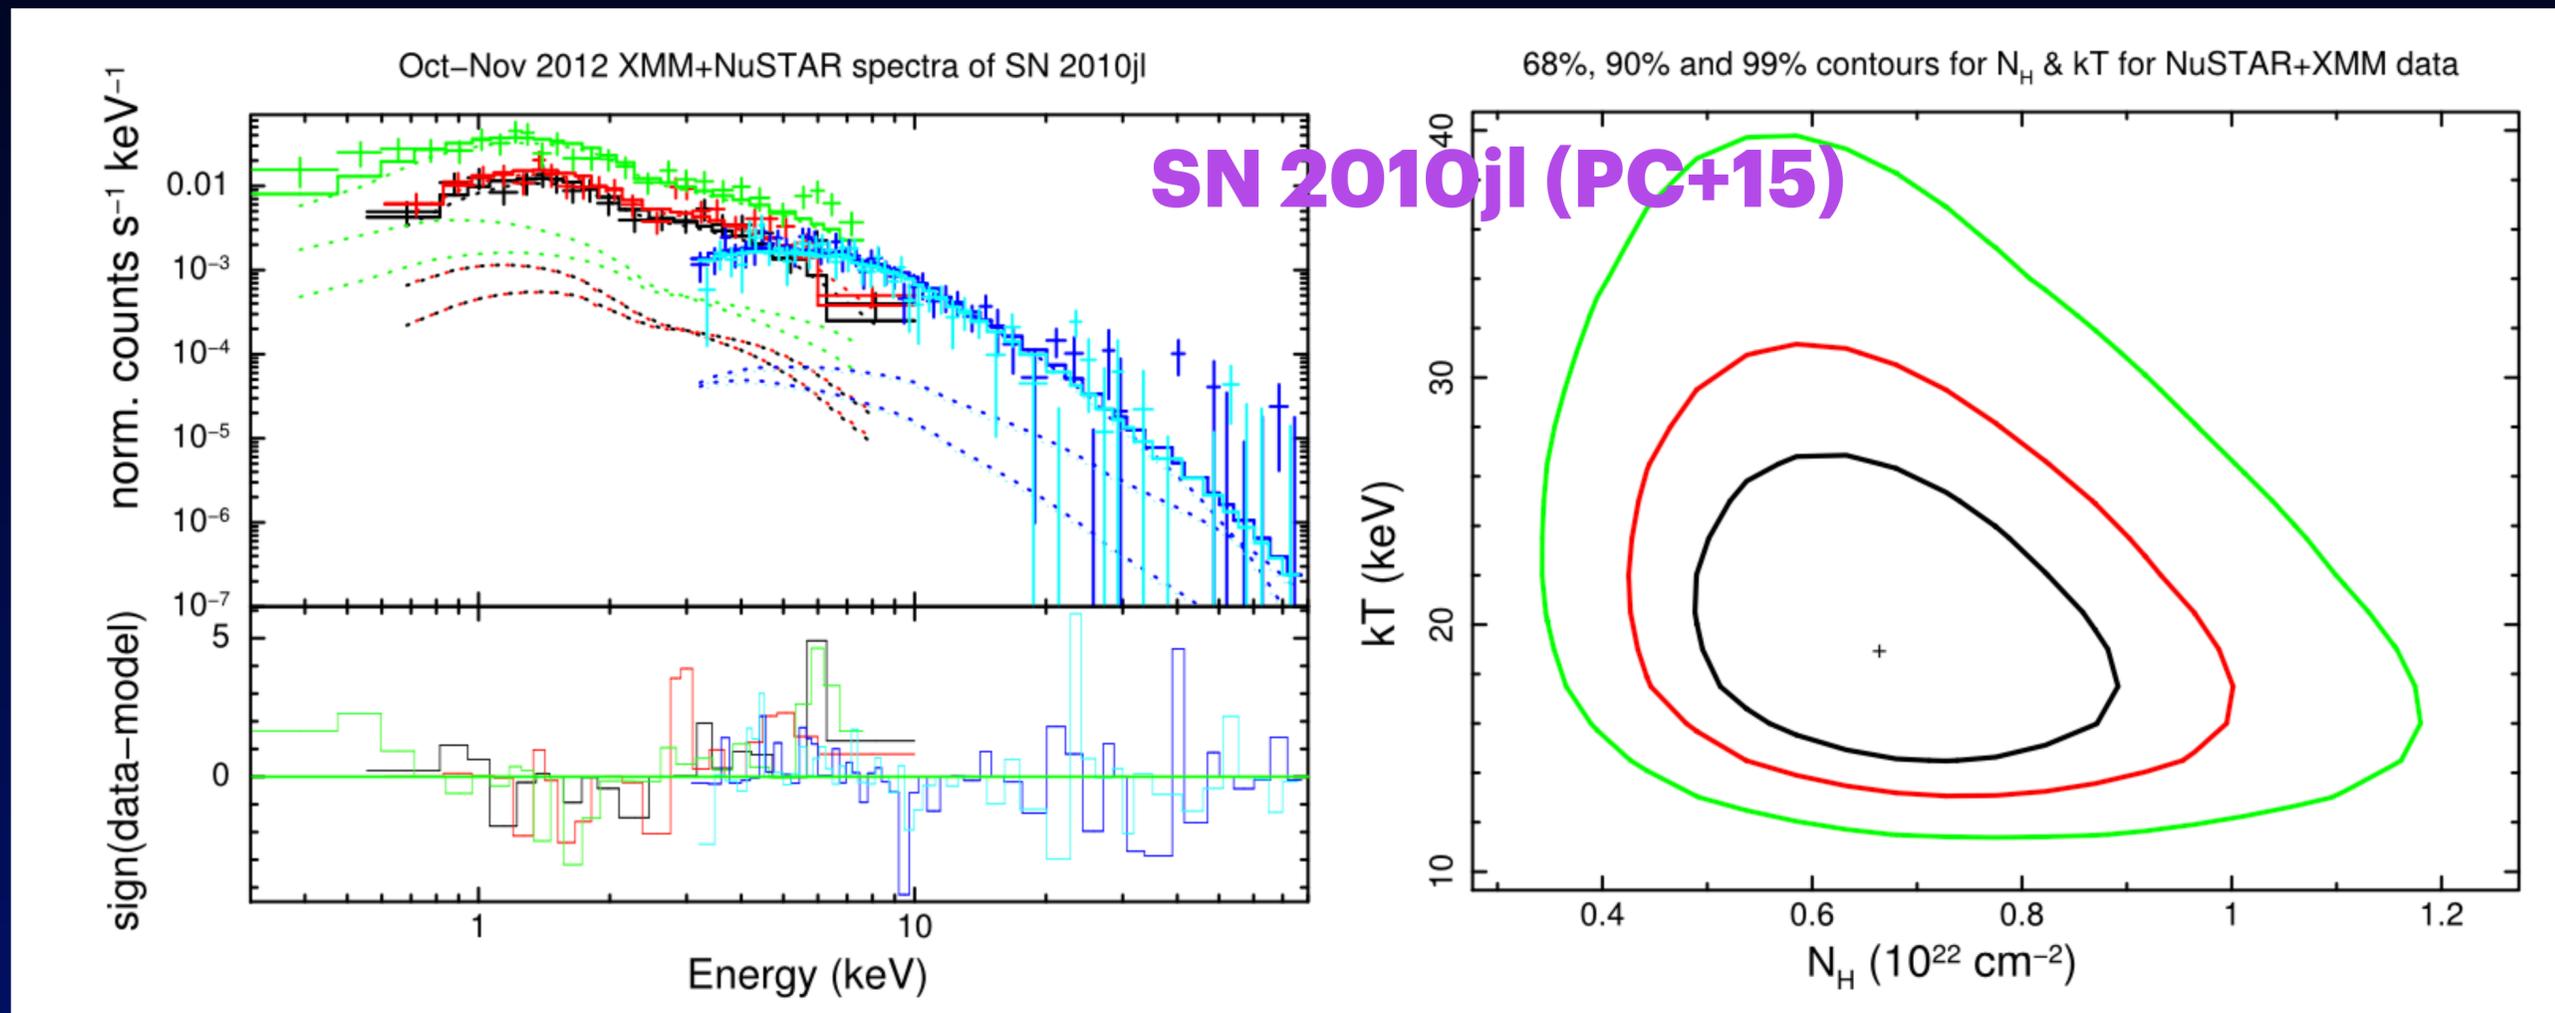

- NuSTAR revolutionary
- Temperature evolution of SN 2014C (Brethauer+22)
- SN 2023ixf - hard X-rays (Grefenstette+23)
- Adiabatic forward shock (PC+23)
- Cooling time - larger for forward shock

SN 2023ixf - Grefenstette+23

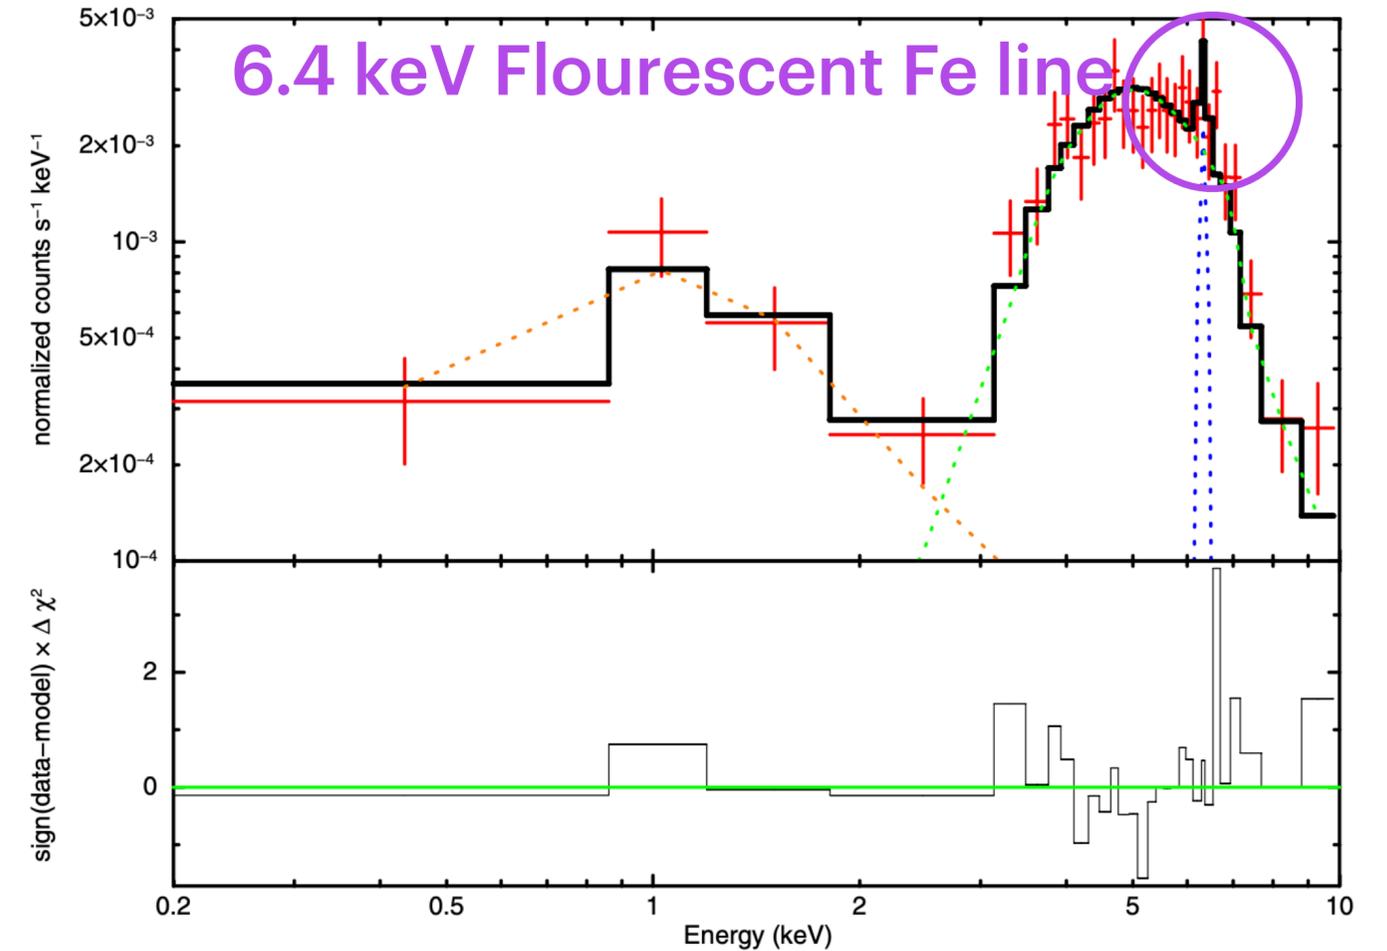

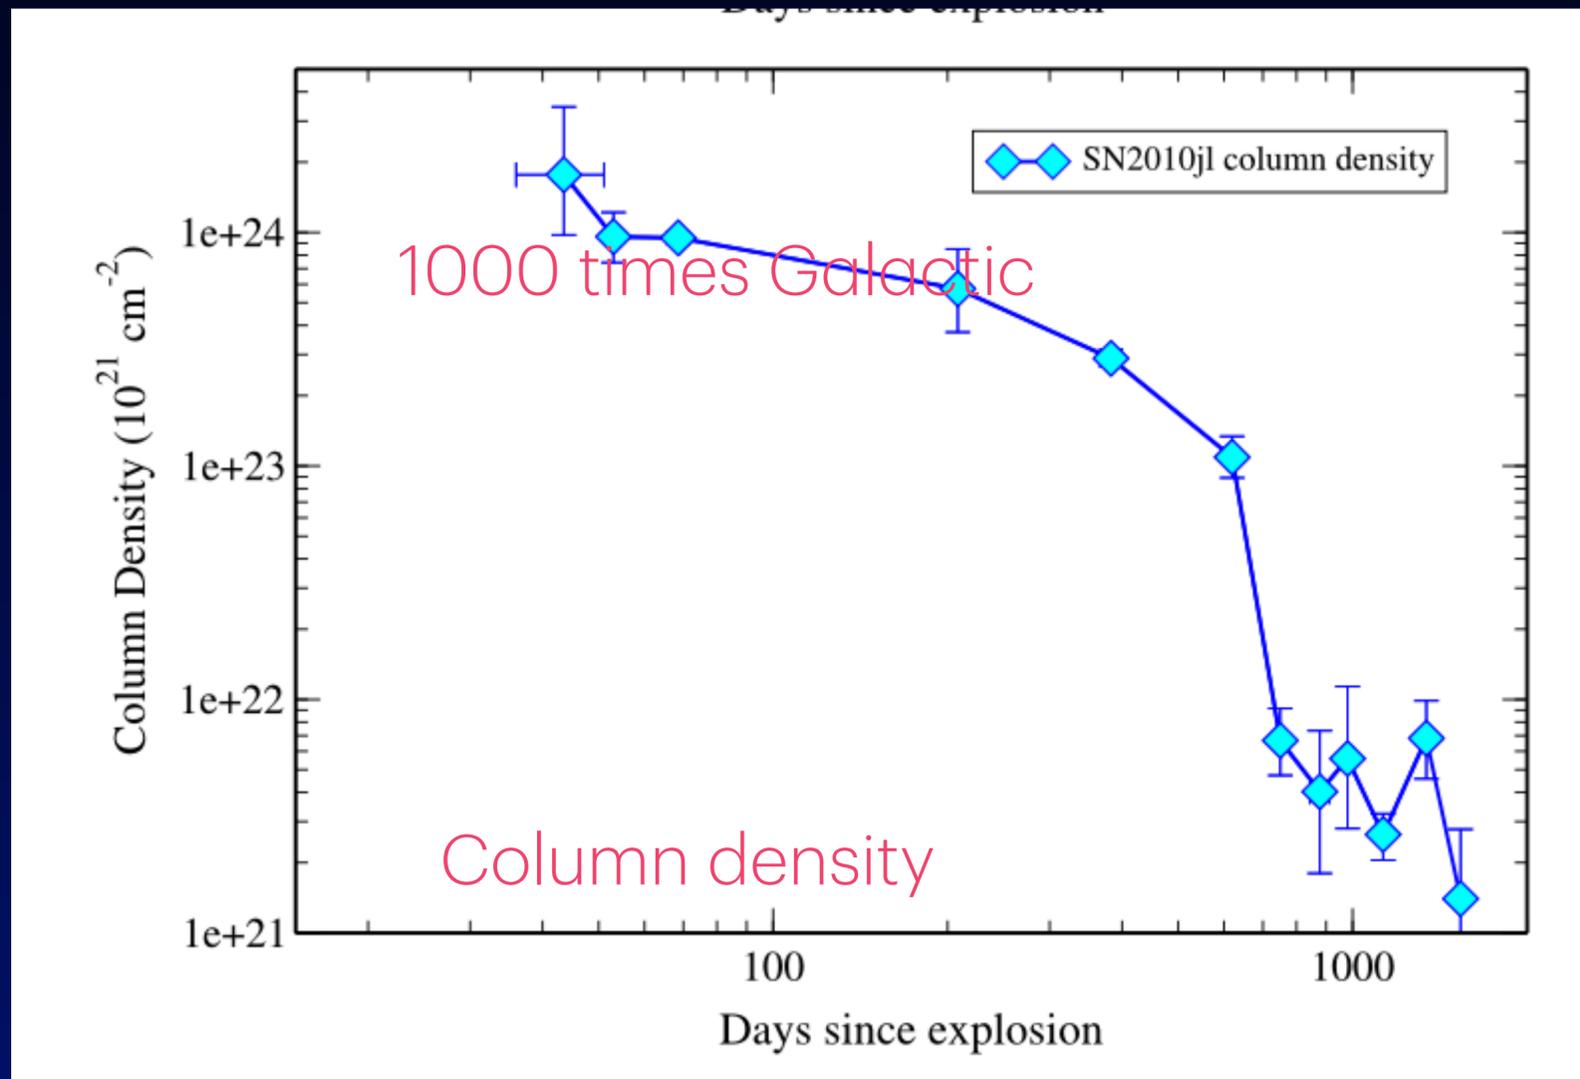

# X-ray emission - circumstellar interaction

Hard X-rays - radiative forward shock (PC+18, PC+15, PC+12)

# X-ray emission - circumstellar interaction

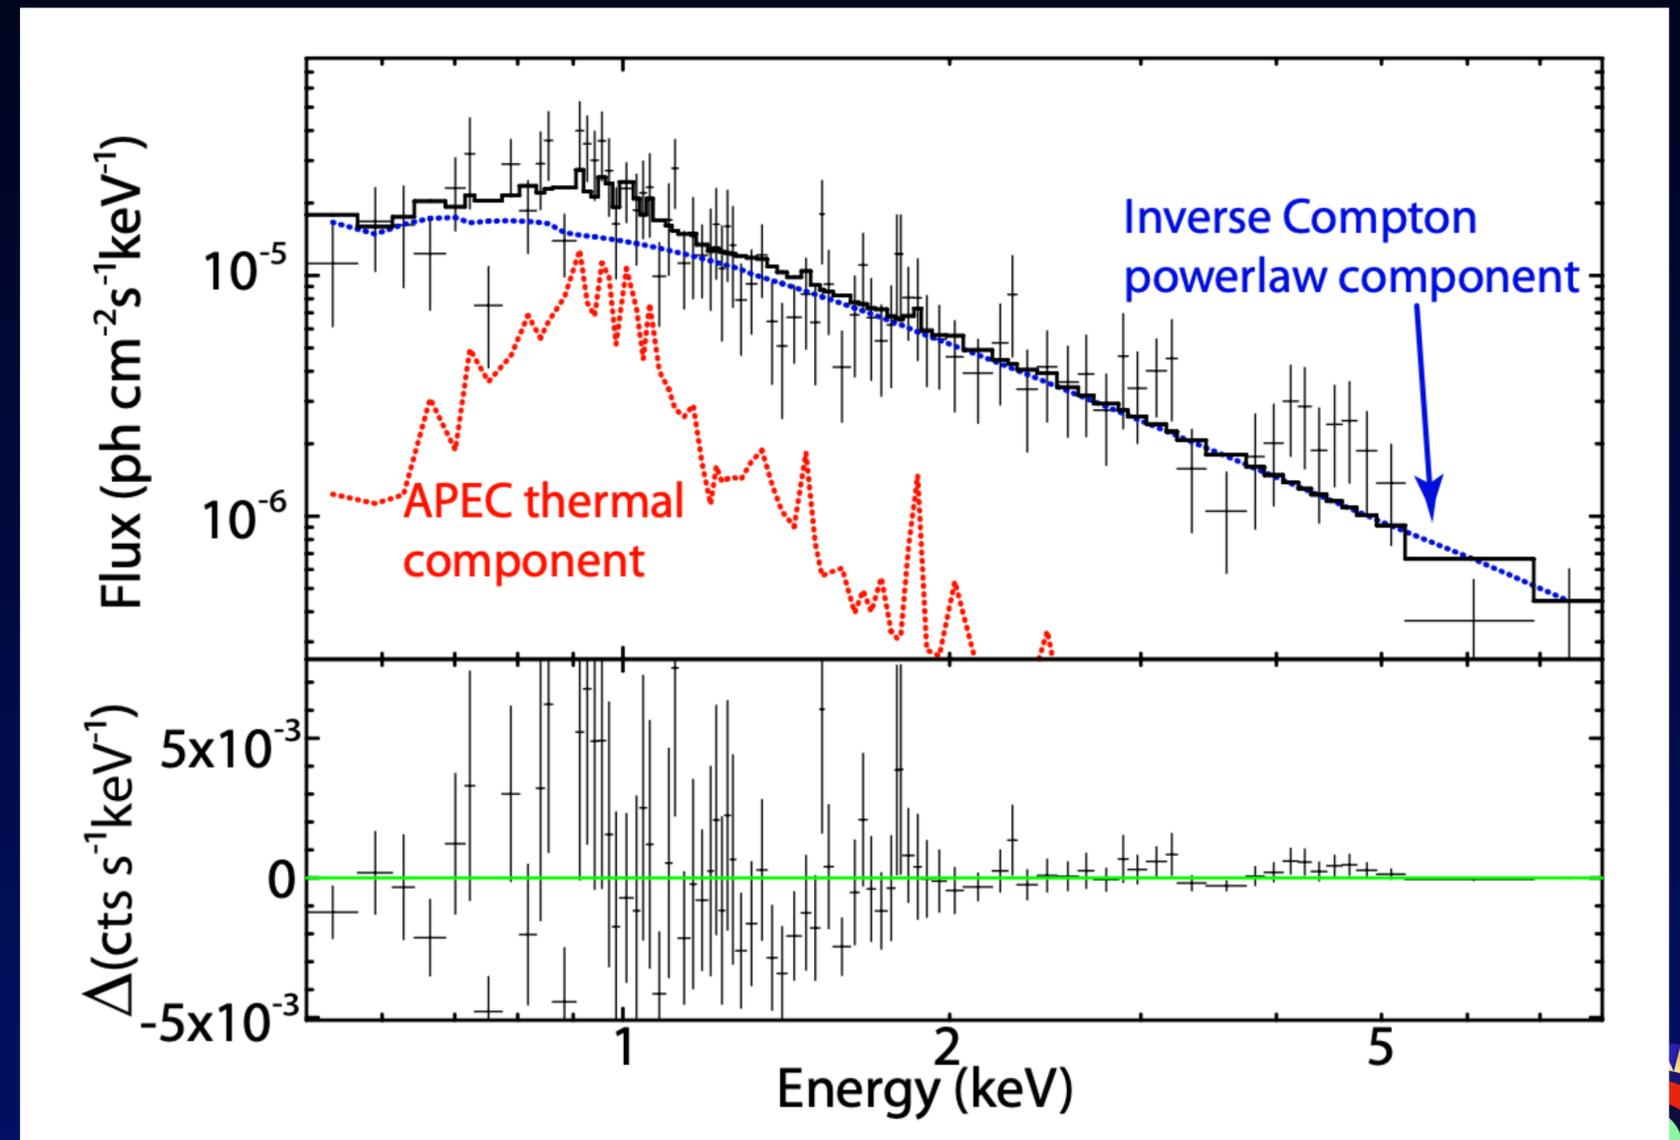

Hard X-rays - radiative forward shock (PC+18, PC+15, PC+12)

# X-ray emission- Circumstellar interaction

## Non-thermal X-rays

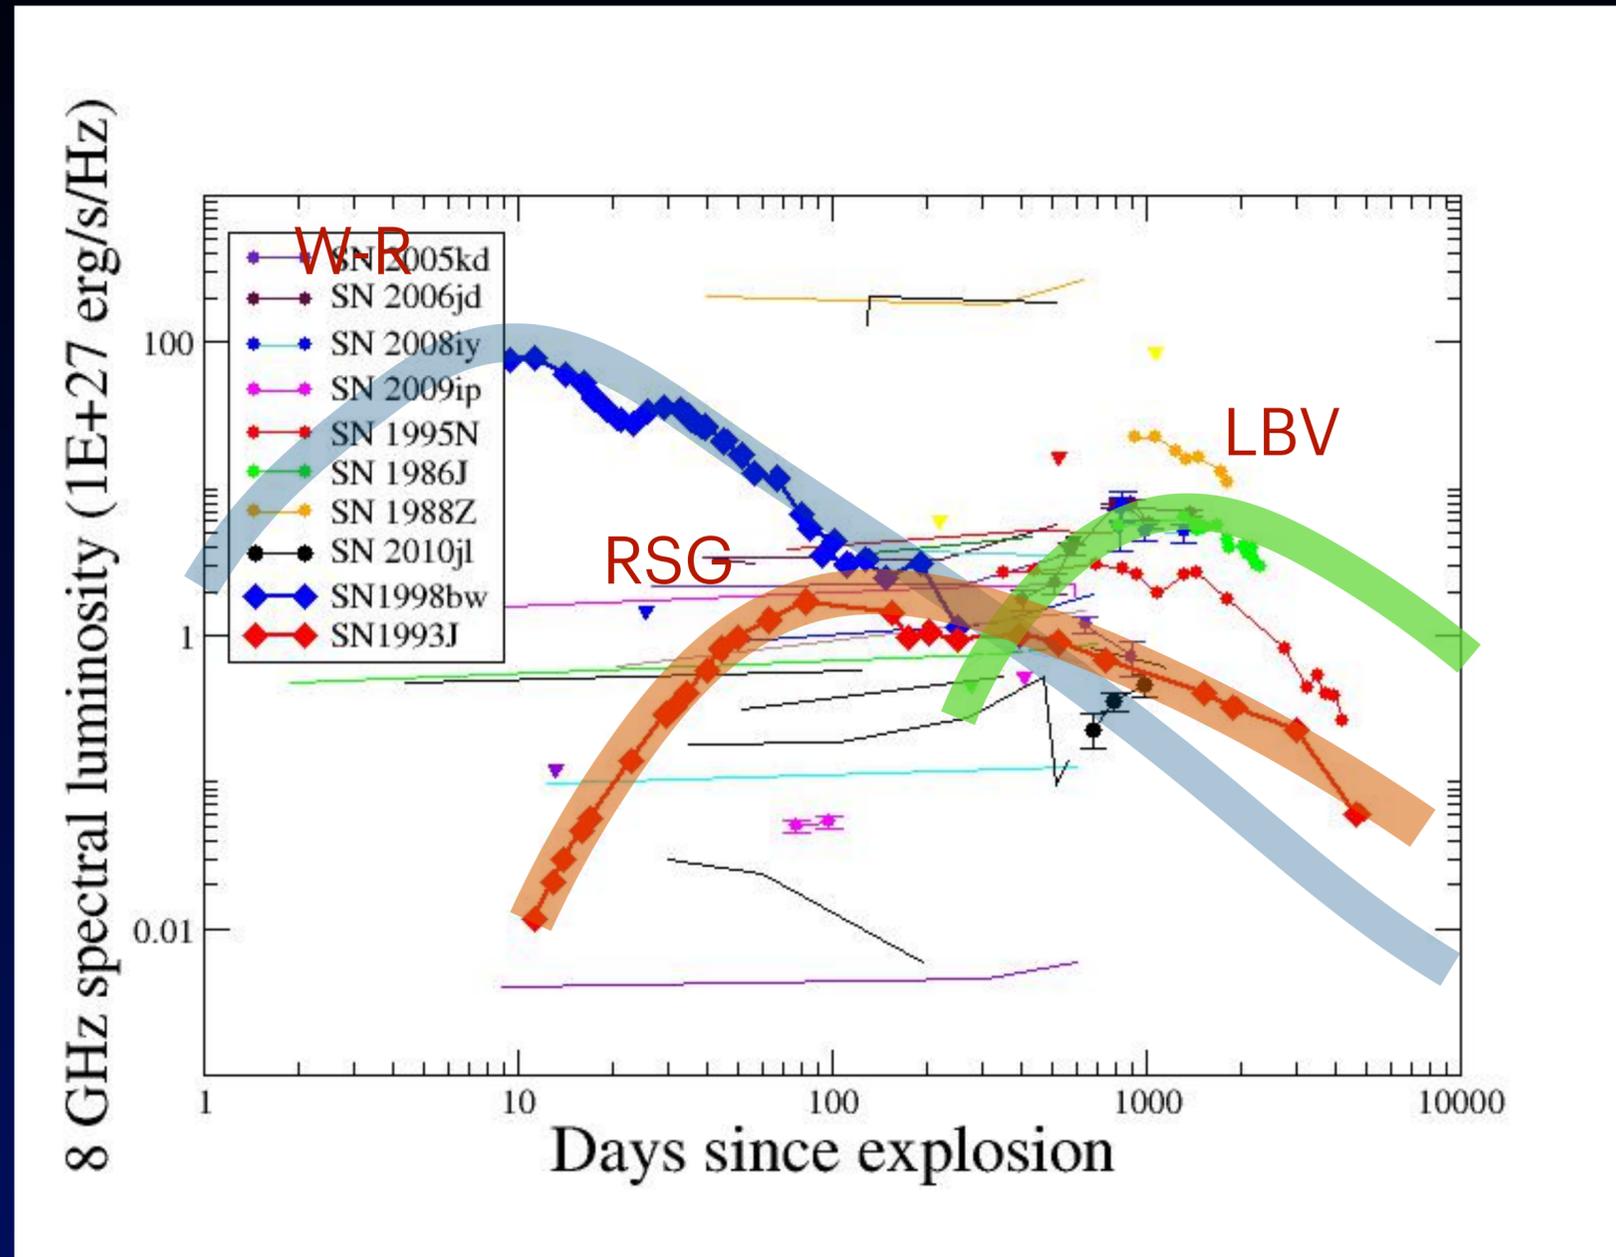

- Inverse Compton component of X-rays
- Usually in type Ib/c supernovae with large ejecta speeds
- Usually in Type II<sup>P</sup> supernovae with large supply of photons
- See Chakraborty+12, 13, Soderberg+11, Margutti+12 etc.

Chakraborty,...PC...2012

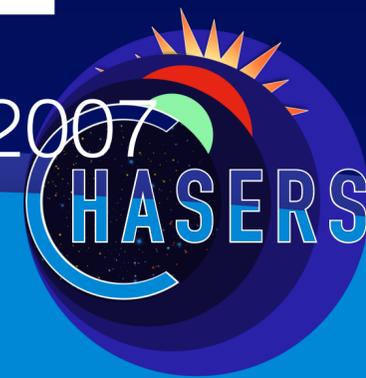

# Radio emission

CSM  $\sim 10^{15}$ - $10^{17}$  cm

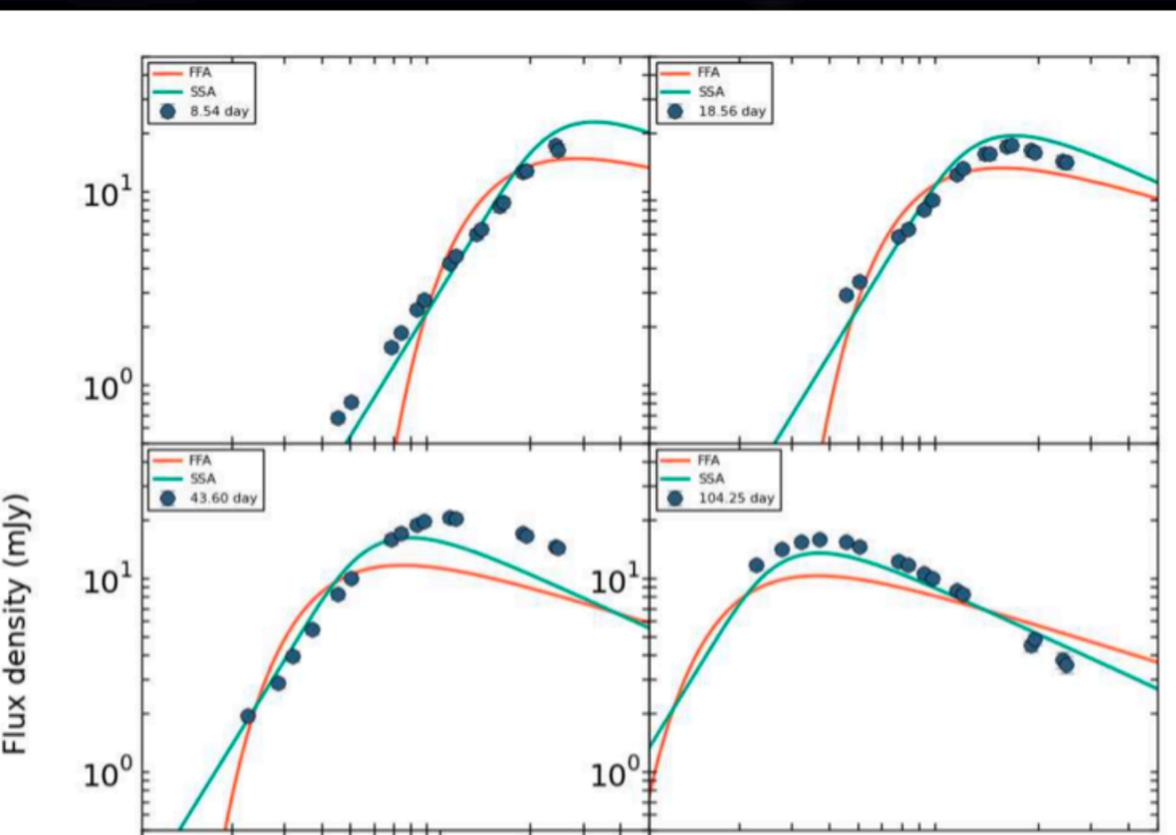

PC 2018, 2025, Bietenholz et al. 2021, Weiler et al. 2007

Image Credit: PC

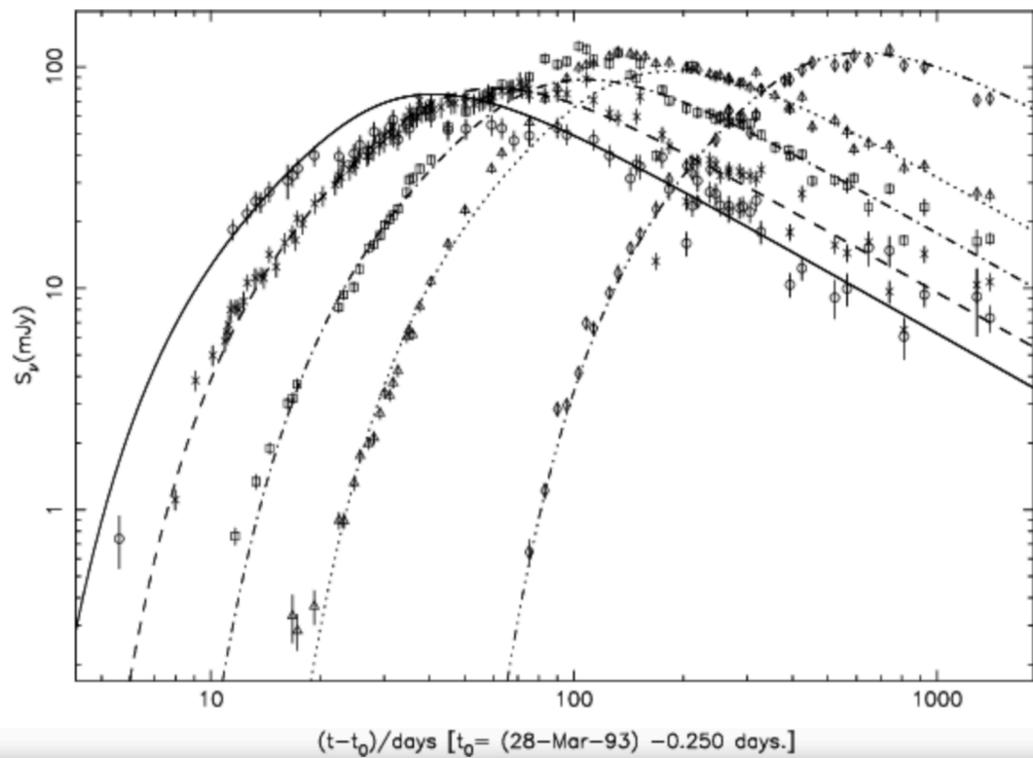

# Absorption of Radio emission

- Synchrotron emission
- Synchrotron self-absorption (fast ejecta, low mass-loss rate, Ib/Ic, IIb etc. see Nayana, PC+, 2022, 2023)
- Magnetic field, size etc

Nayana, PC+22

# Absorption of Radio emission

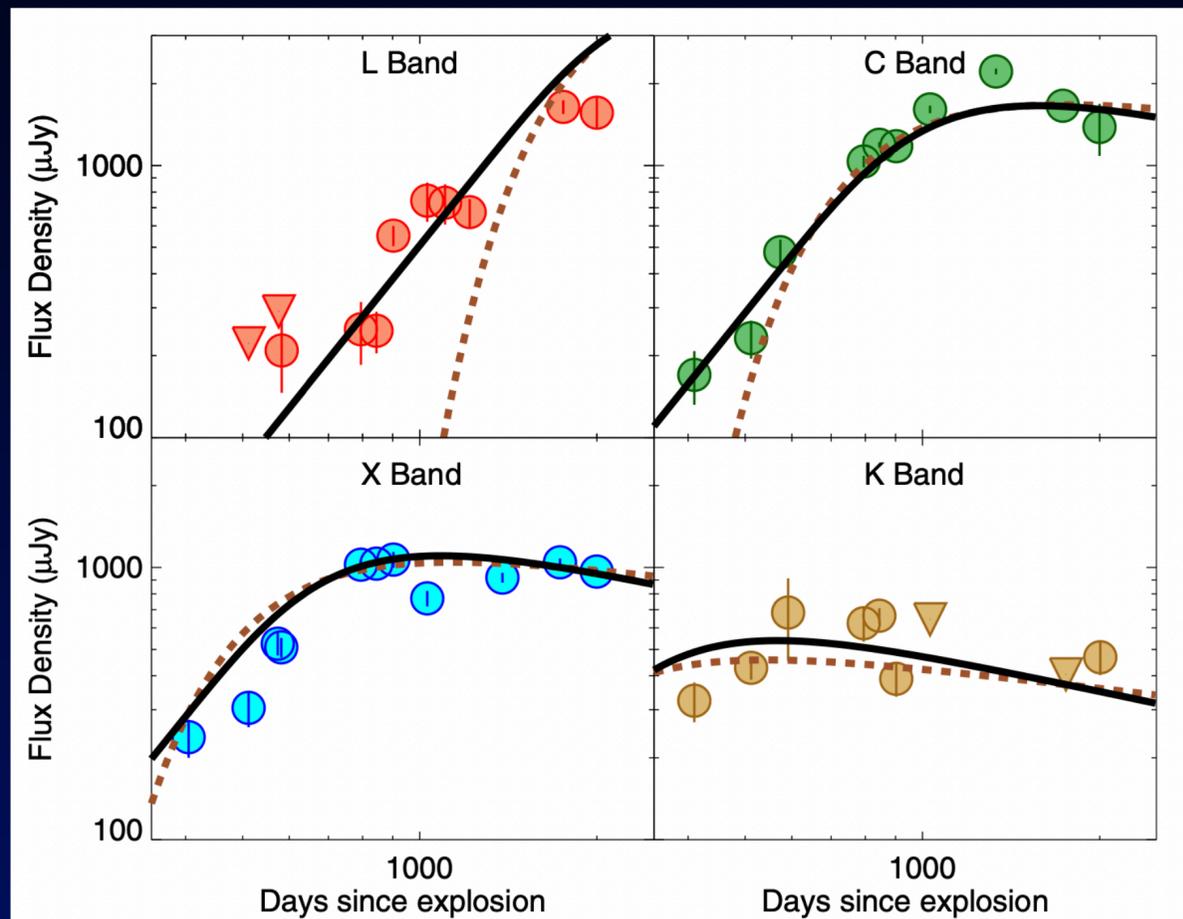

Weiler+02

- Synchrotron emission
- Synchrotron self-absorption (fast ejecta, low mass-loss rate, Ib/Ic, IIb etc. see Nayana, PC+, 2022, 2023)
  - Magnetic field, size etc
- Free-free absorption (slow ejecta, large mass-loss rate)
  - Density of the medium, mass-loss rate

# Absorption of Radio emission

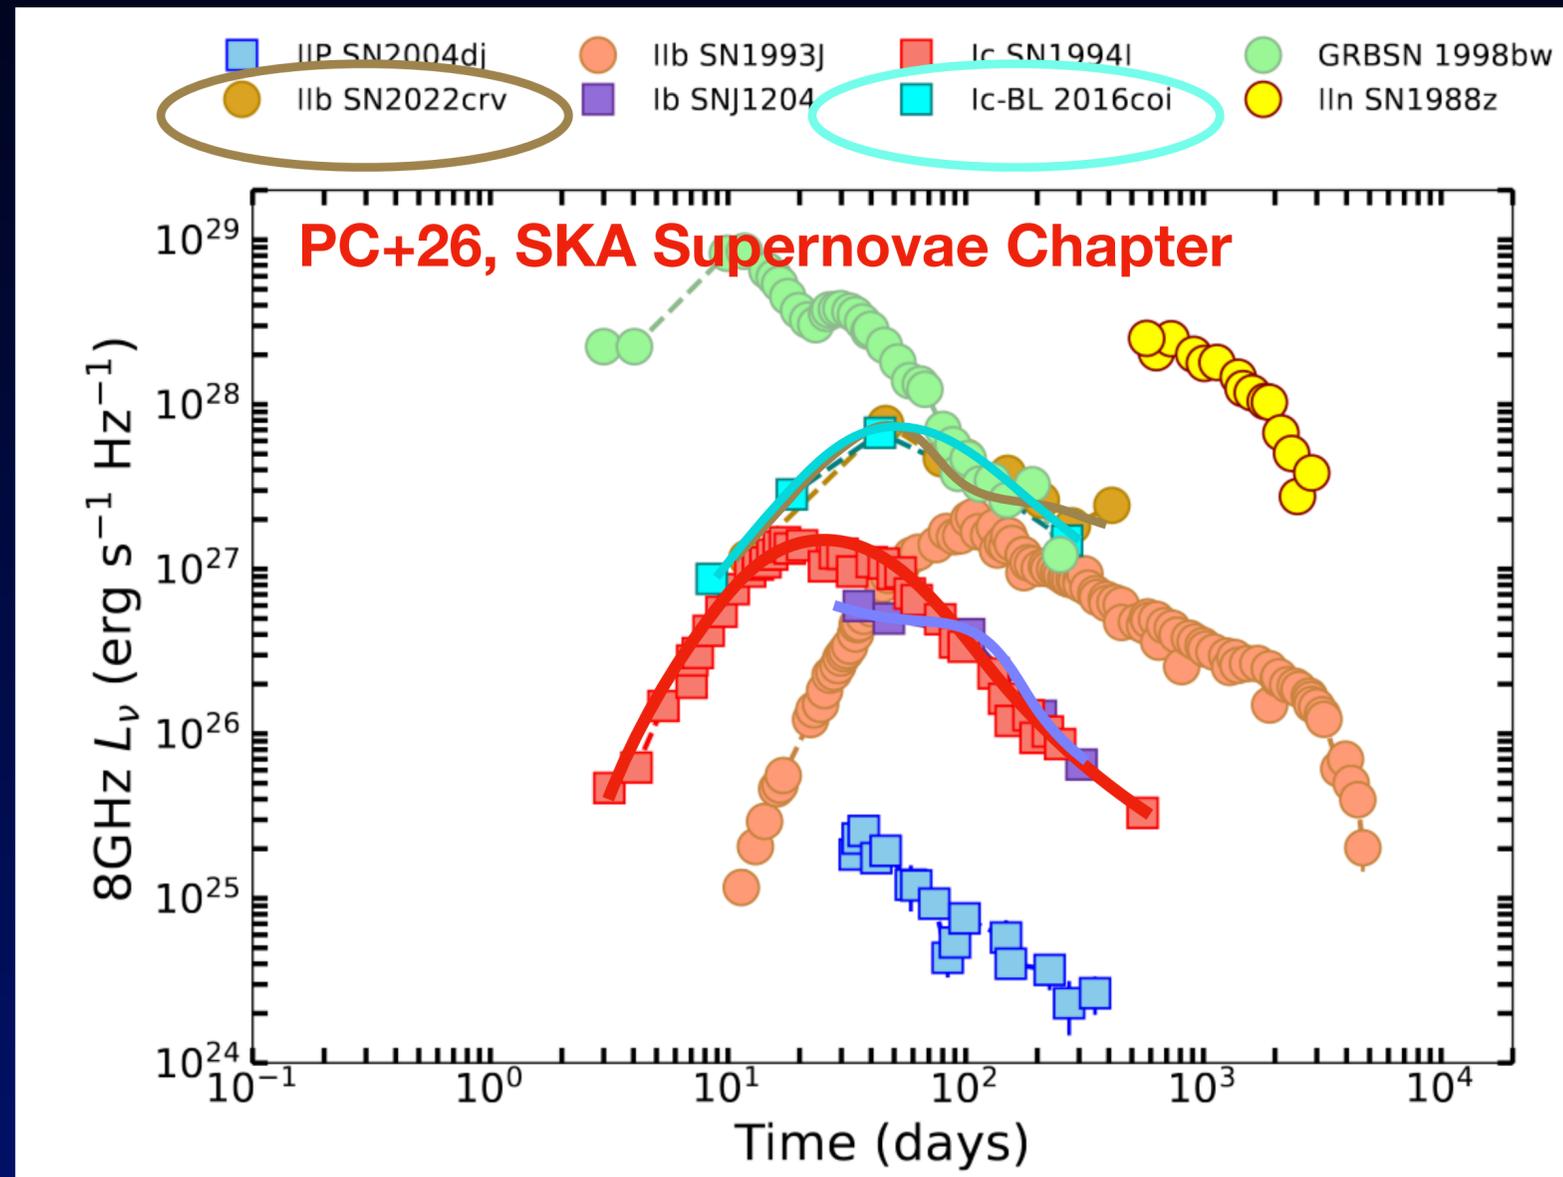

- Synchrotron emission
- Synchrotron self-absorption (fast ejecta, low mass-loss rate, lb/lc, llb etc. see Nayana, PC+, 2022, 2023)
  - Magnetic field, size etc
- Free-free absorption (slow ejecta, large mass-loss rate)
  - Density of the medium, mass-loss rate
- Internal free-free absorption (radiative shock, cool dense shell, mixing of cool gas)

PC+12, PC+18, Baer-way, PC 2025

$$M_a \approx 2 \times 10^{-8} T_4^{5/2} M_{\odot}$$

# Absorption of Radio emission

- Degeneracy in physical parameters
- Early peak due to high velocity (derived from SSA) can mimic the early peak due to low density CSM (derived from FFA)
- True understanding to physical environments about supernovae

# Compact CSM - also seen in ALMA mm bands

- Radio absorption SSA -  $F_\nu \propto R^2 B^{-1/2} \nu^{5/2}$ ,  $B \propto \rho_{\text{CSM}}^{1/2}$ ,  $F_\nu \propto \rho_{\text{CSM}}^{-1/4}$

- Radio absorption FFA -  $\tau_{\text{ff}} \propto \rho_{\text{CSM}}^2$ ,  $F_\nu \approx F_{\nu, \text{intrinsic}} e^{-\tau_{\text{ff}}}$

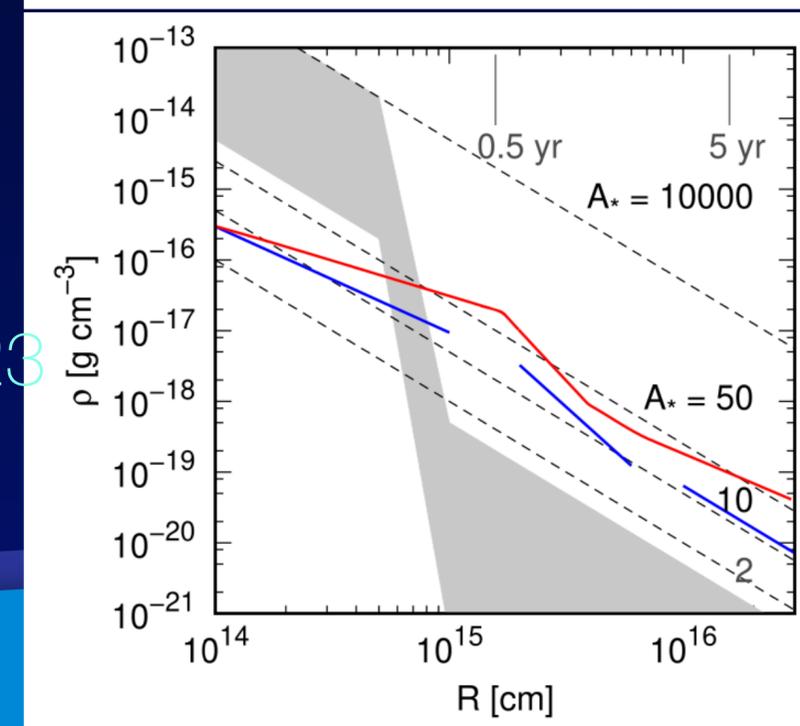

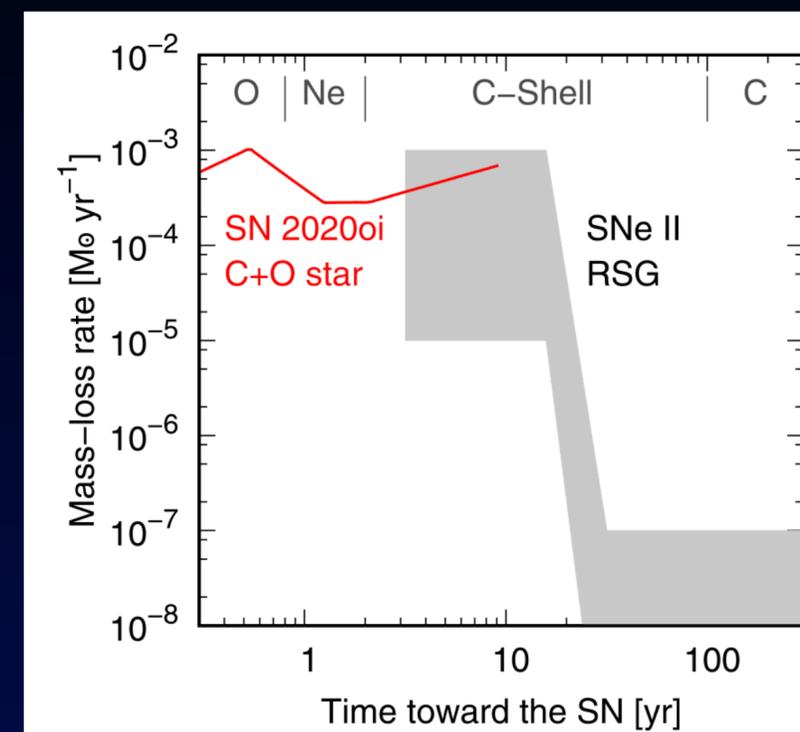

- Optically thin flux -  $F_\nu \propto \rho_{\text{CSM}}^{(p+5)/4}$

- Early studies possible with ALMA

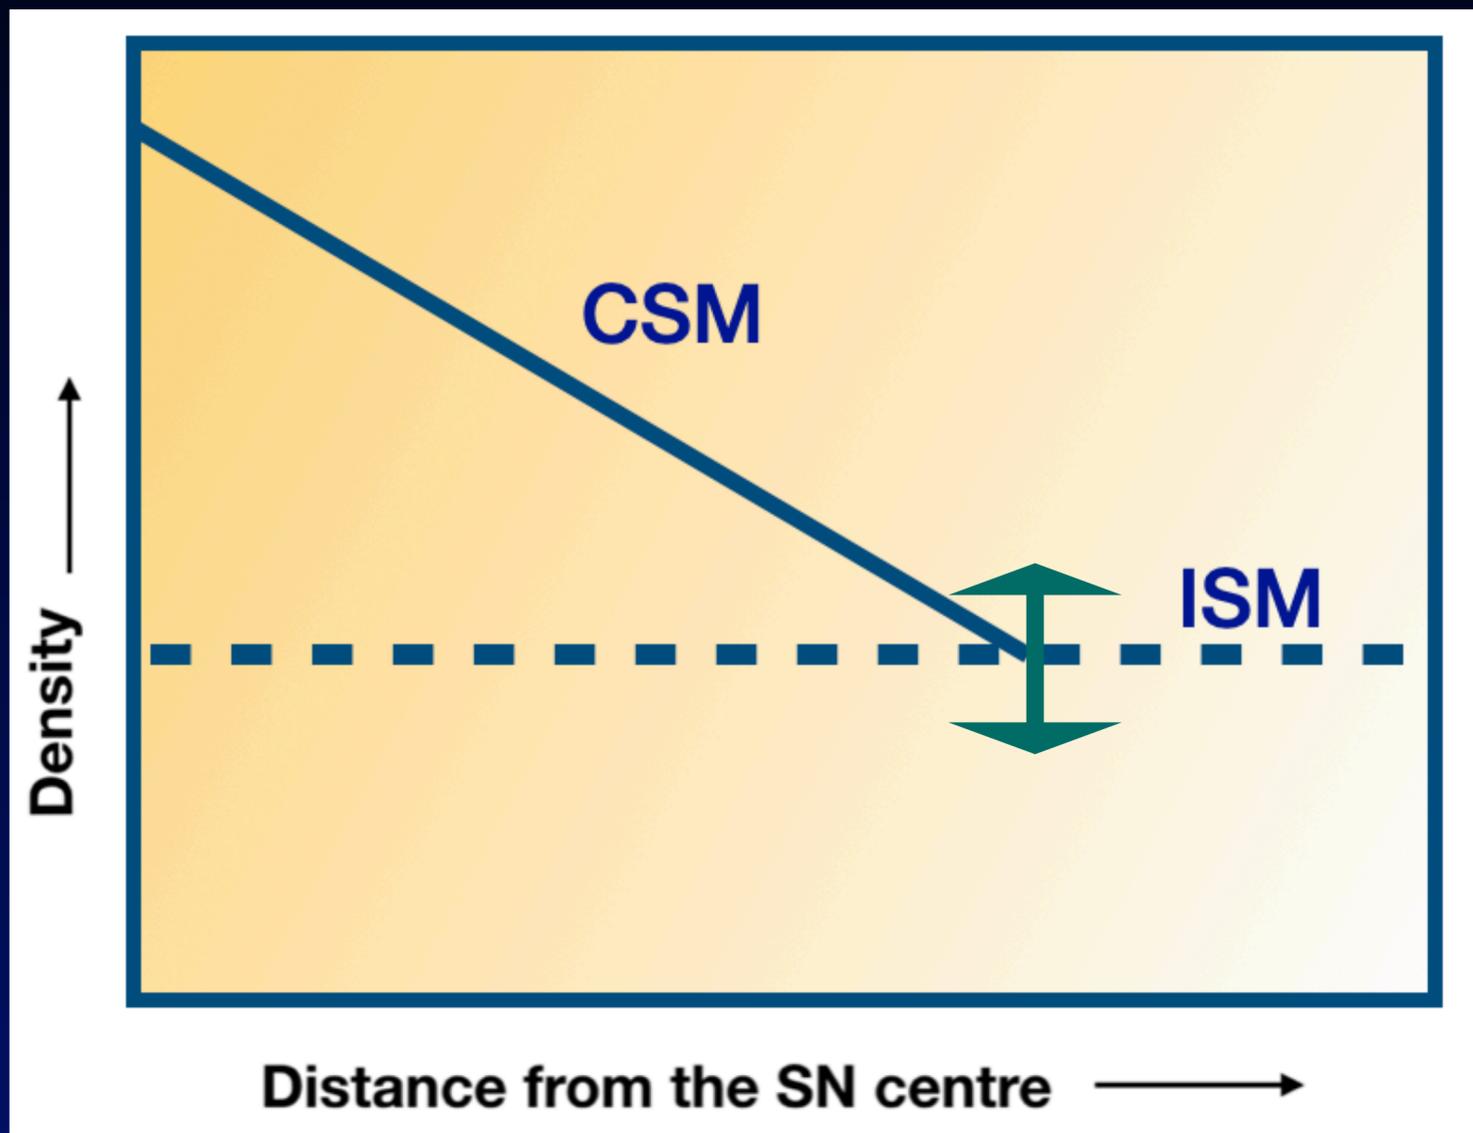

- SN 2020oi (Ic) - Maeda, PC+21

- SN 2018ivc (III-L->IIb)- Maeda, PC+23, Maeda, Michiyama, pc+23

- SN 2020oi - enhanced mass-loss seen - Maeda, PC+21

# Extent of CSM - radio observations

- Late time radio emission in various supernovae
- VLASS - Stroh et al. 2021 - 19 supernovae - up to 40 years old
- ASKAP - Rose et al. 2024 - 7 rebrightening SNe - oldest 30 years old
- Extent of the CSM - how long mass-loss rate

# Extent of CSM - implications of binary

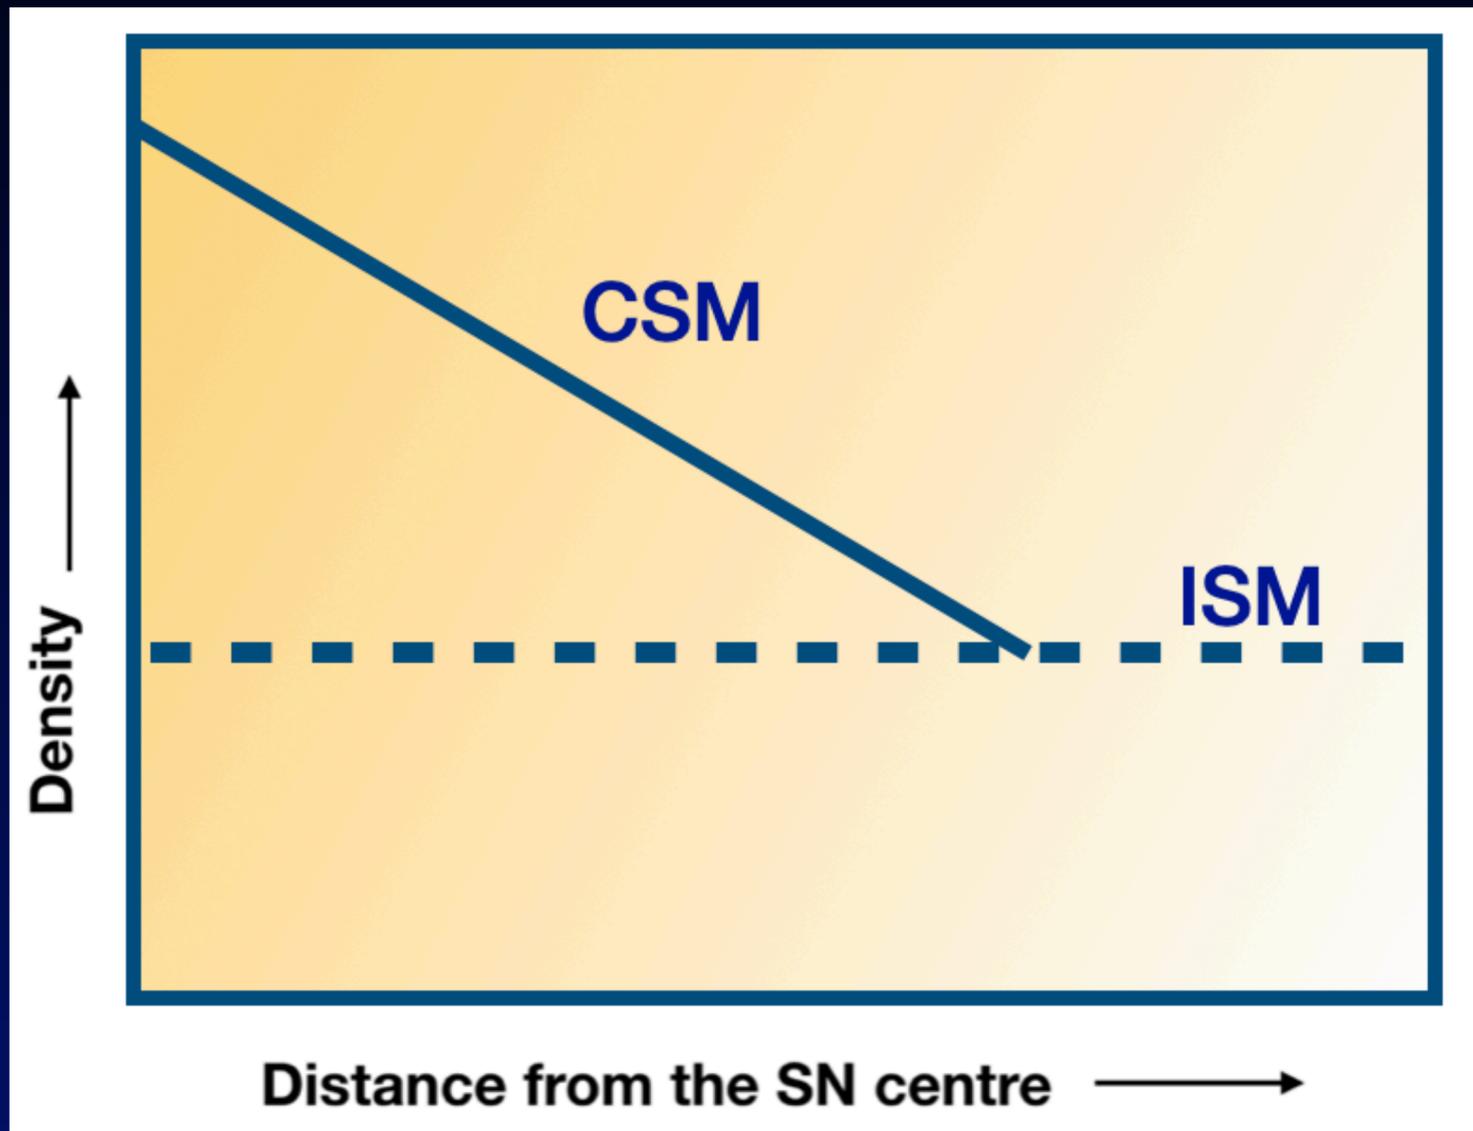

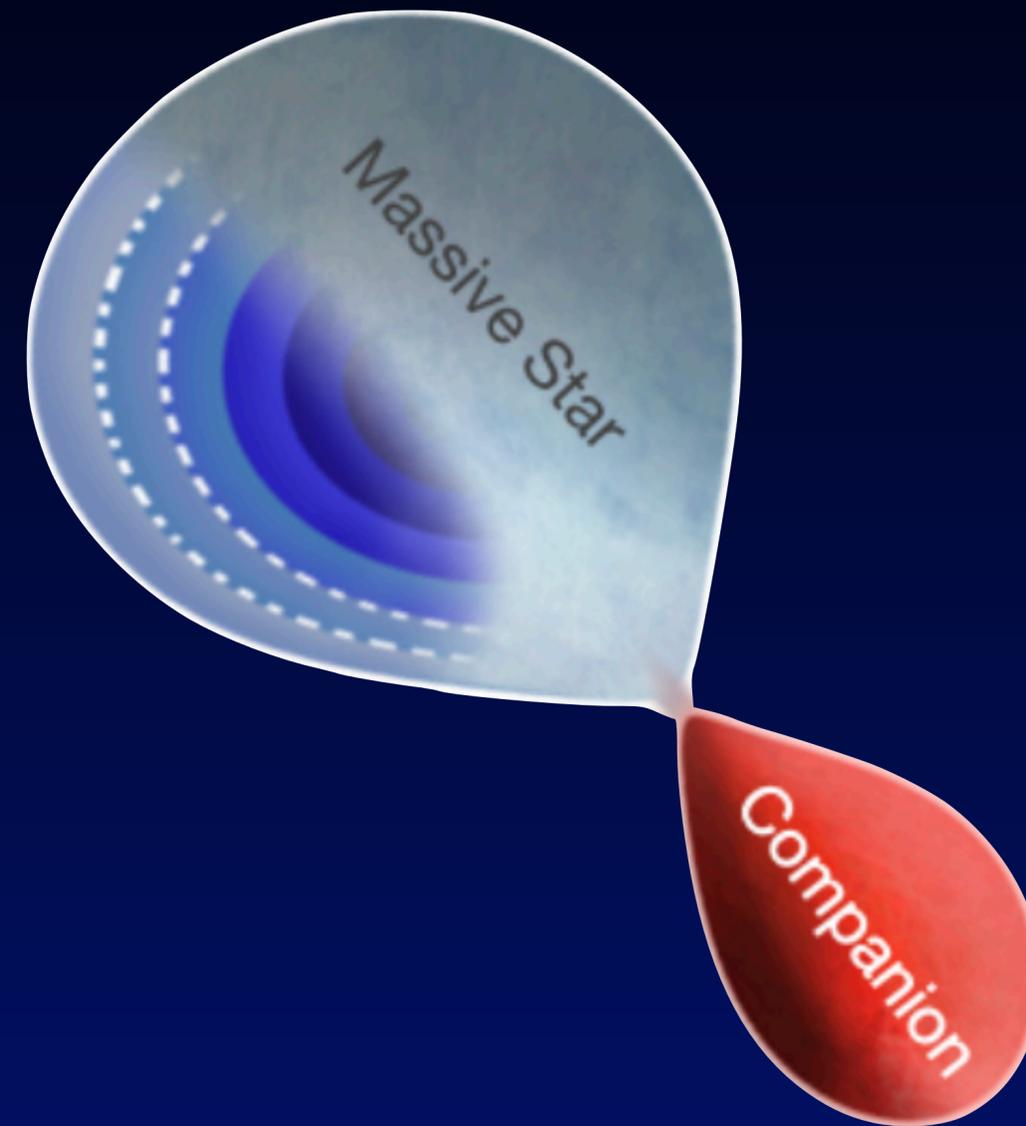

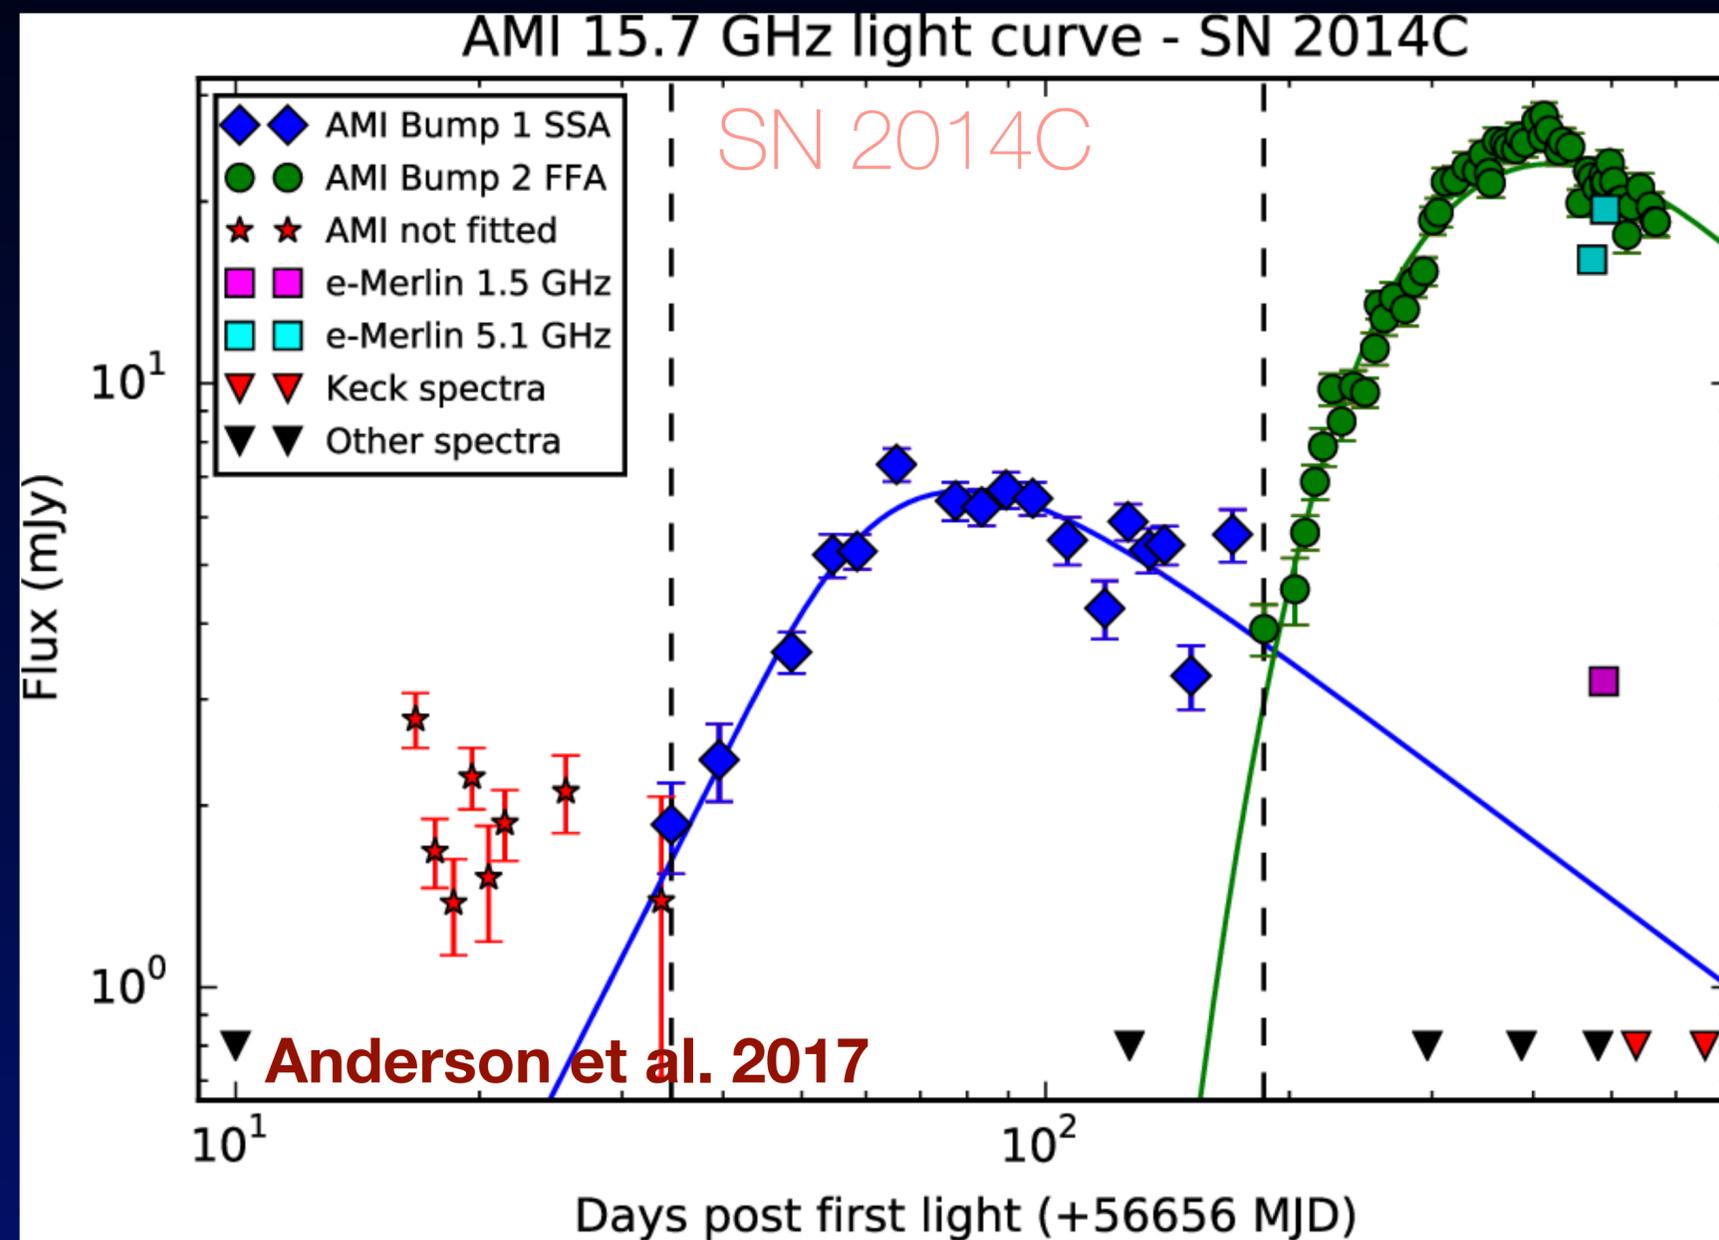

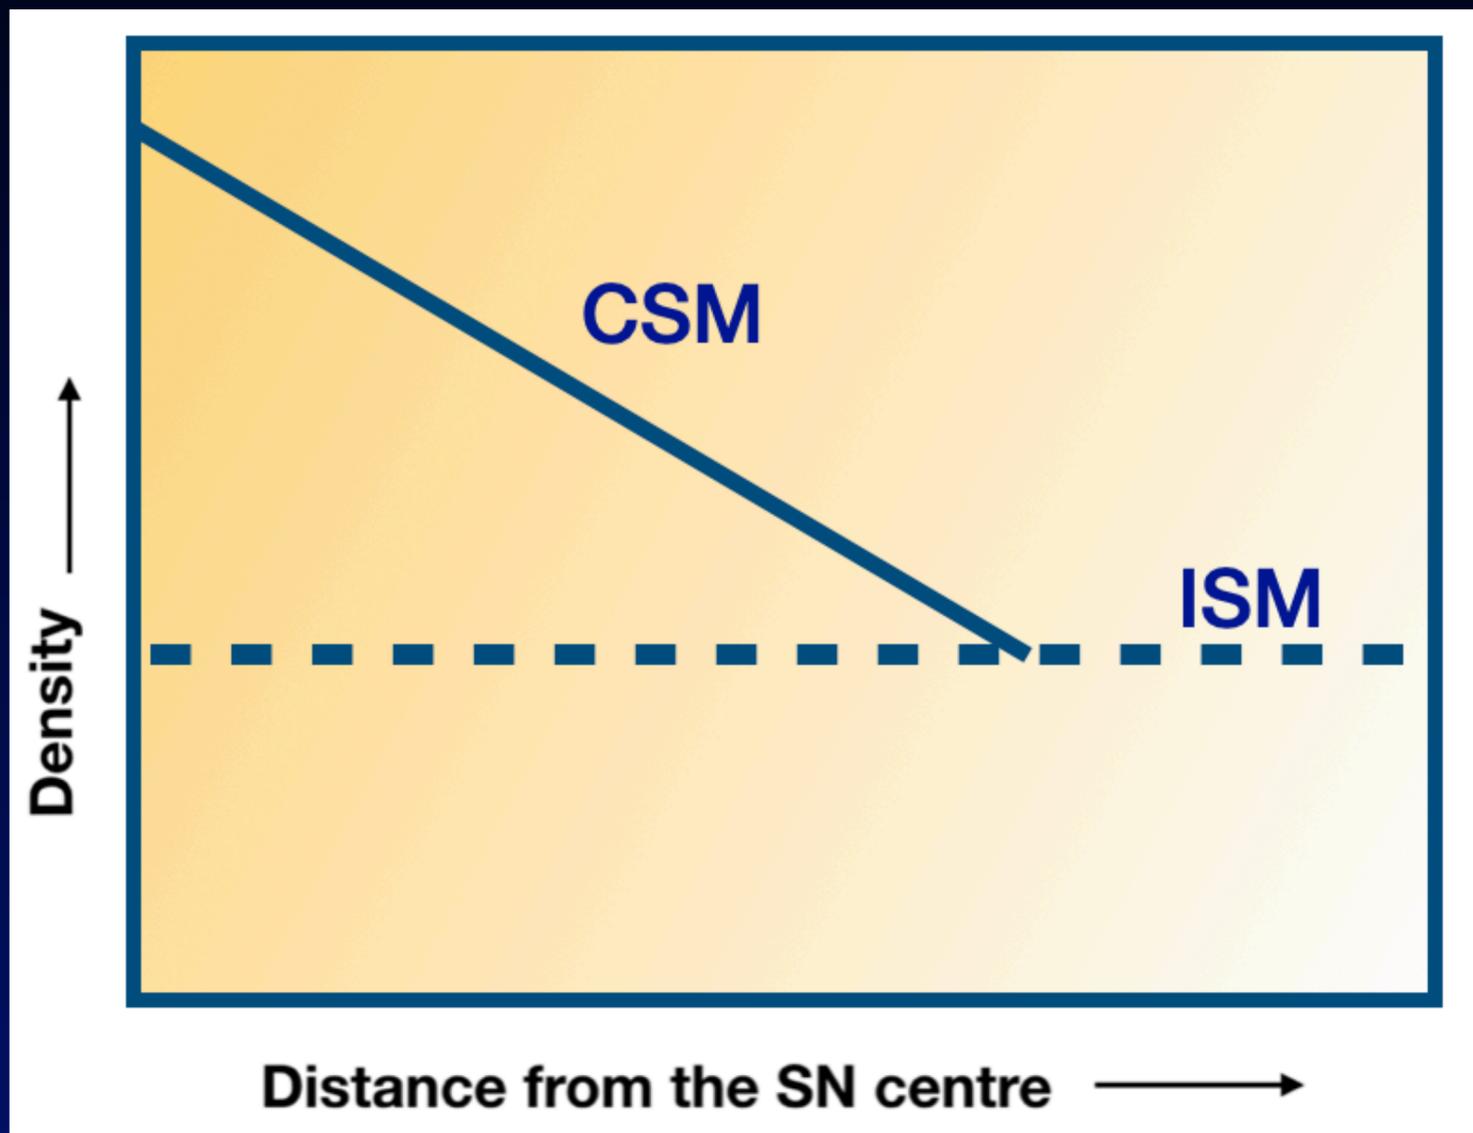

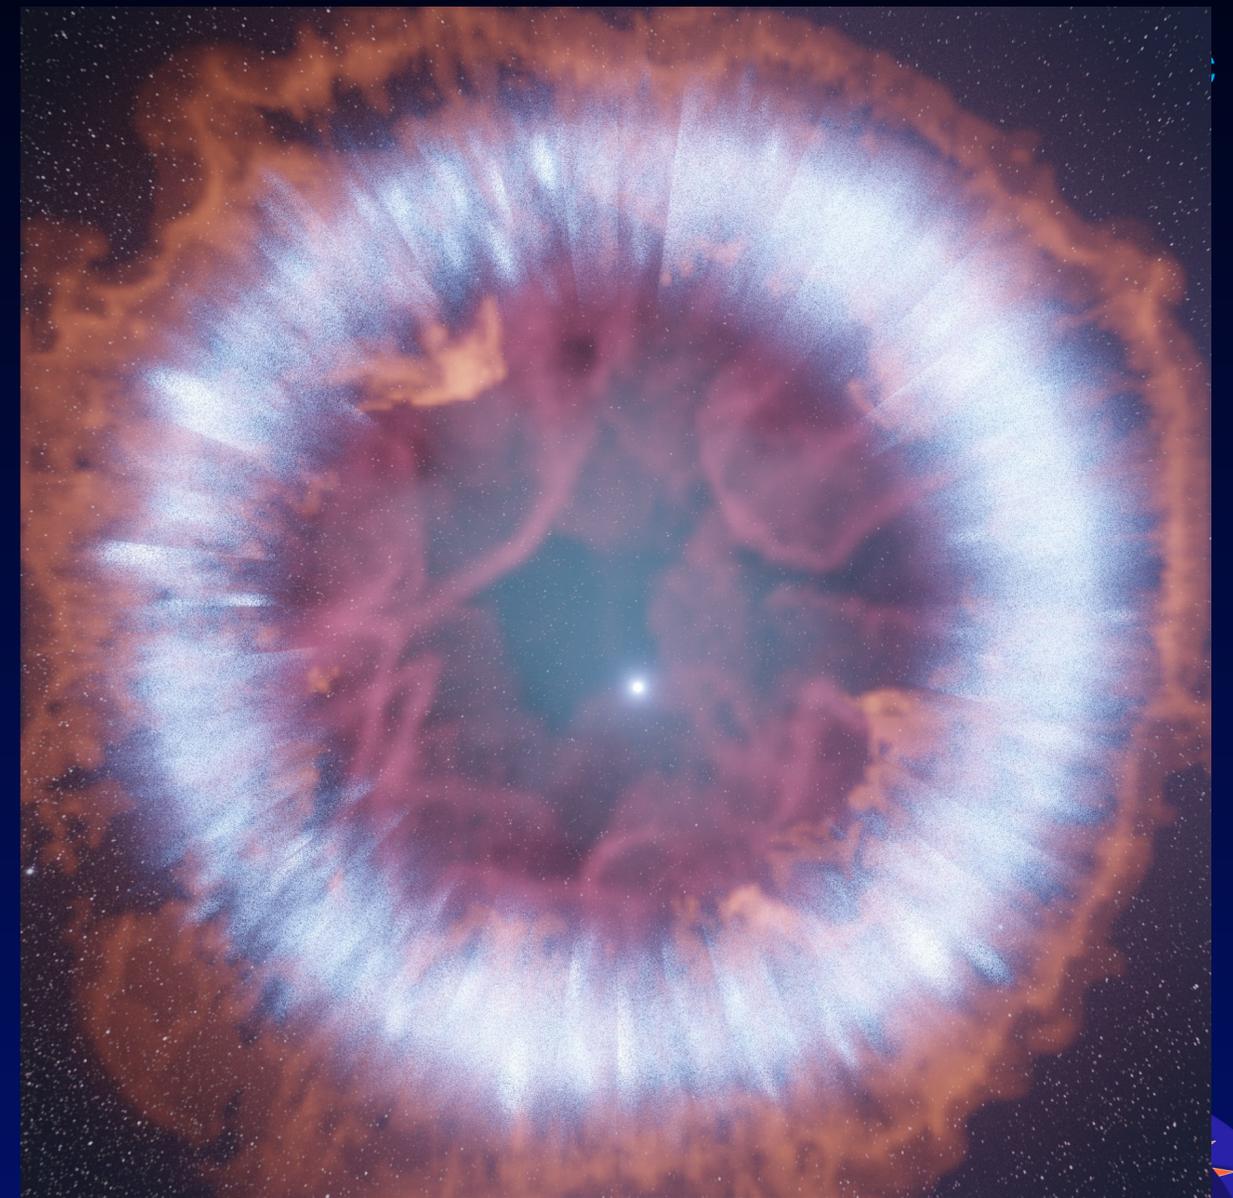

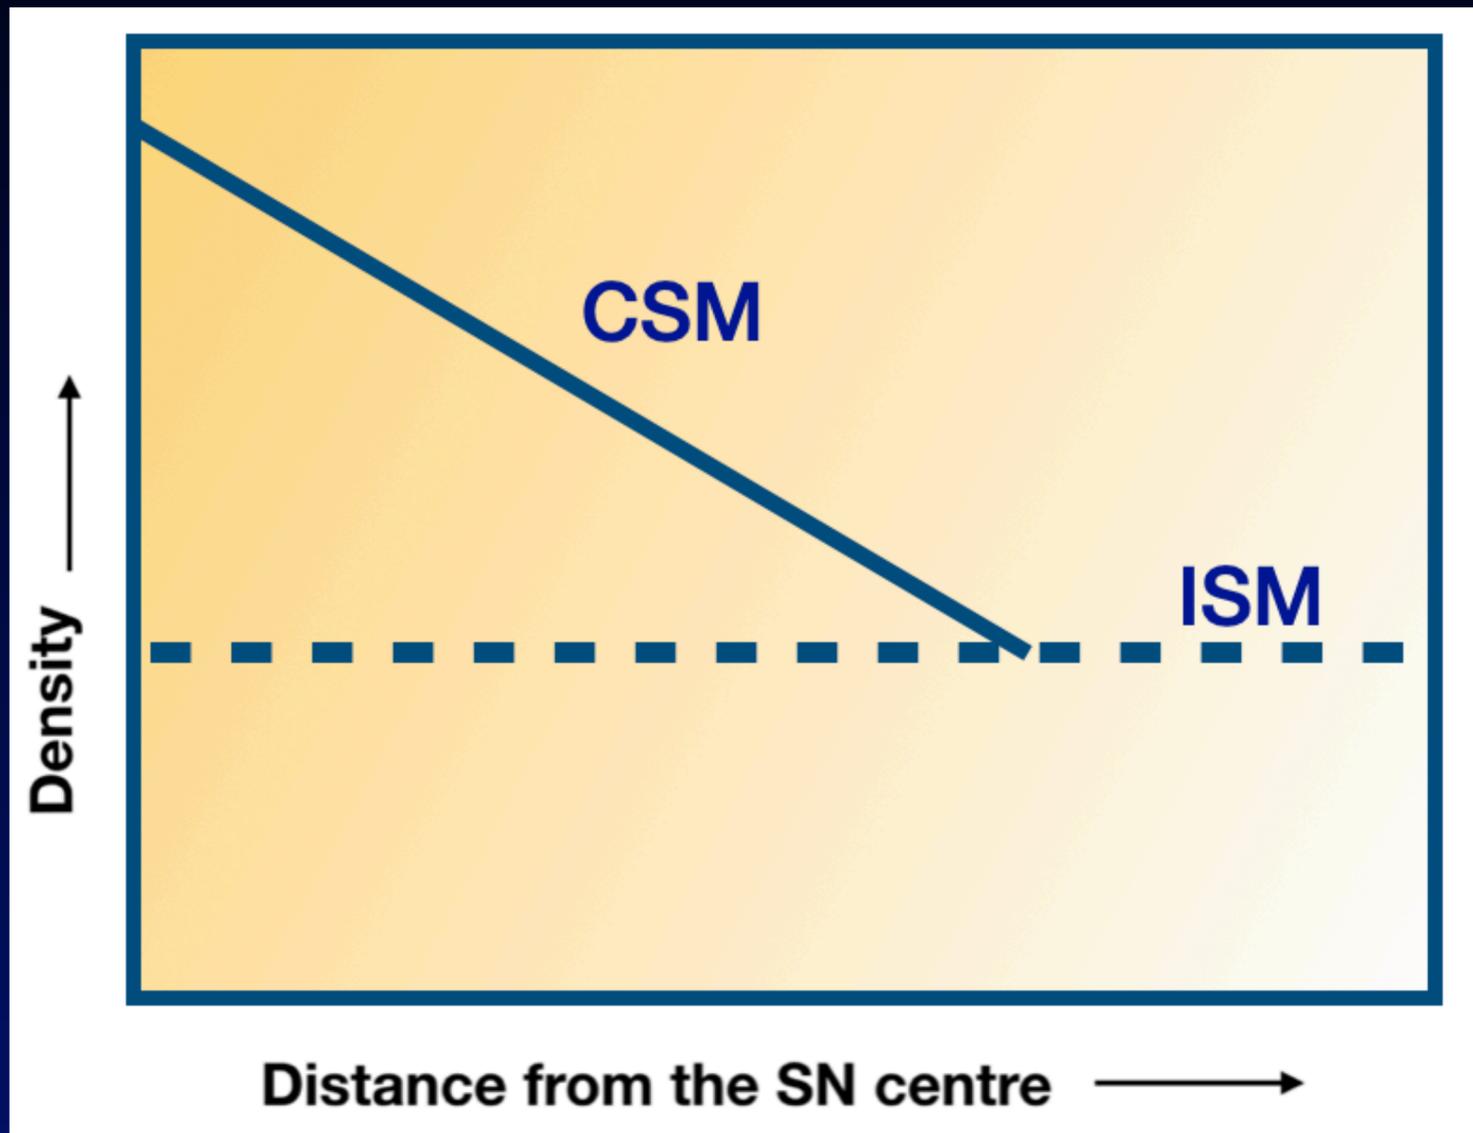

Image Credit:PC

# CaSTs - Calcium rich supernovae

Sahana Kumar, Baer-way, ... PC ... arXiv:2601.19018

- CaSTs - strong calcium features and notably weak oxygen features
- Physical origins of CaSTs - thermonuclear or core collapse
- SN 2025cof - one of the nearest Ca-rich
- SN 2025cof shows spectral signatures characteristic of Type Ib SNe
- Radio, Xray (GMRT, VLA, SwiftXRT, optical) — third X-ray bright

# CaSTs - Calcium rich supernovae

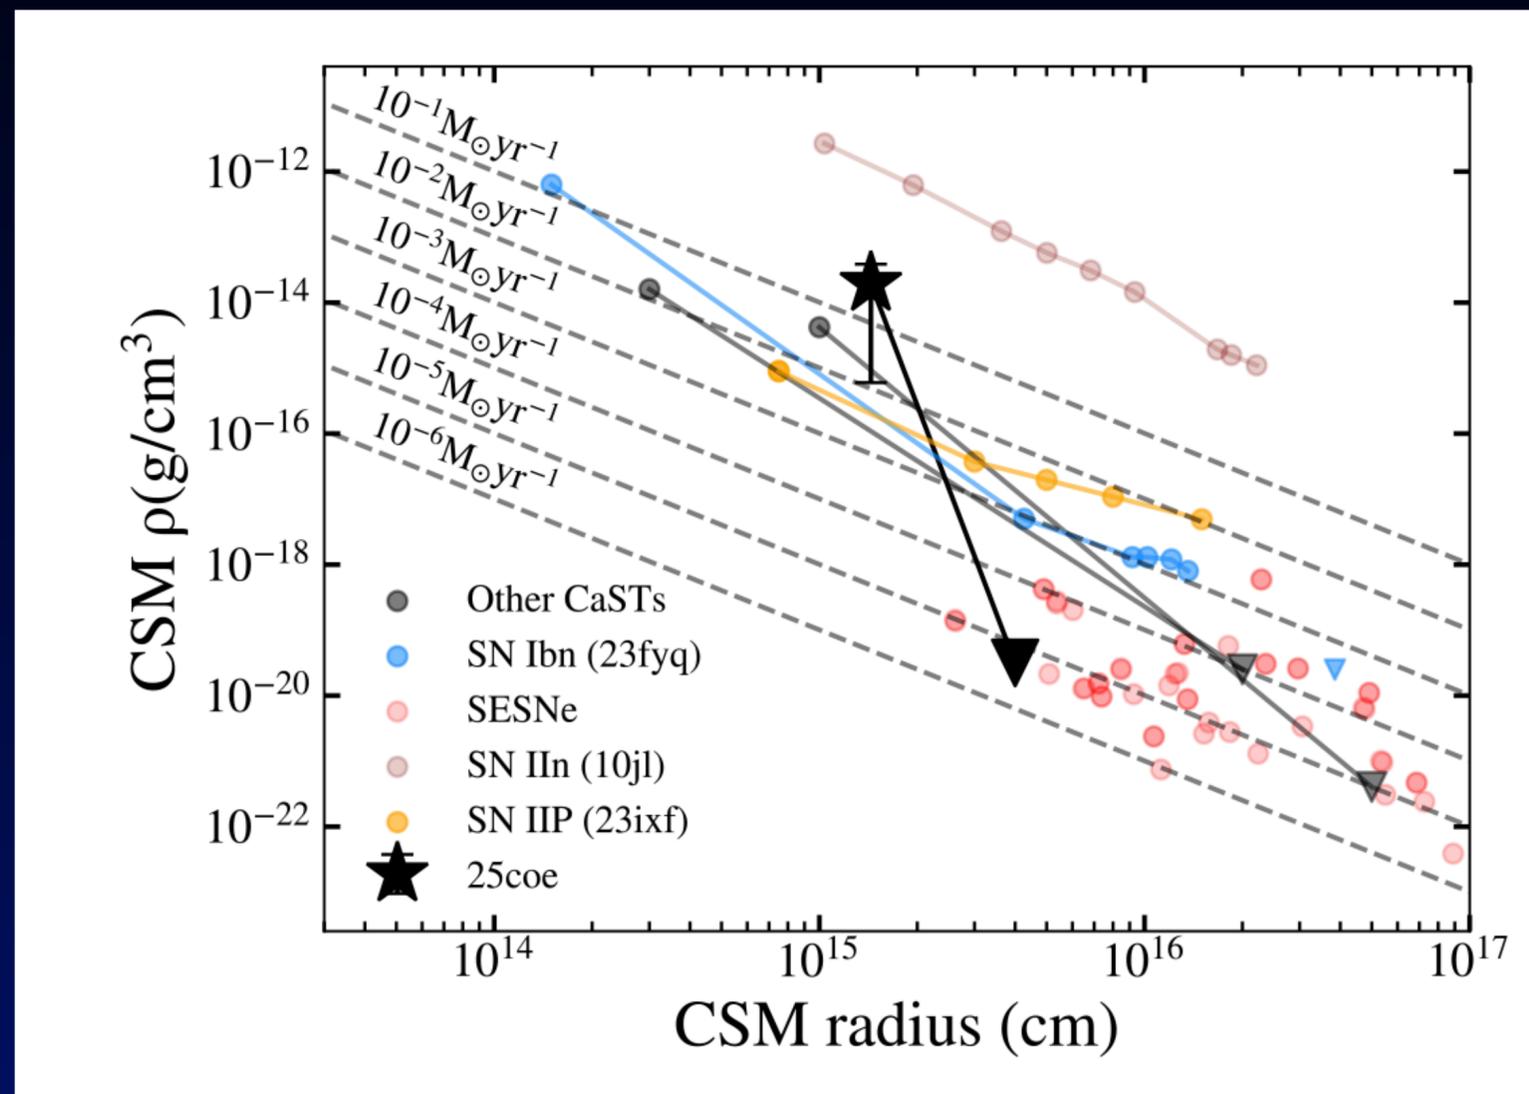

Sahana Kumar, Baer-way, ... PC ... arXiv:2601.19018

# CaSTs - Calcium rich supernovae

Sahana Kumar, Baer-way, ... PC ... arXiv:2601.19018

- Radio to X-ray  $0.12 M_{\odot}$  material within  $>2 \times 10^{15} \text{cm} - <4 \times 10^{15} \text{cm}$  extent of CSM
- Around  $0.2 - 0.5 M_{\odot}/\text{yr}$  if the mass was lost directly in the last 100-200 days before the explosion

# Supernovae progenitors constraints

- SNe IIn - enhanced mass-loss rate few centuries before explosion
- SNe Ibn/Icn - envelope expulsions years before explosion
- SNe Ib, Ic - envelopes stripped long before explosion
- CaSTs - not known - thermonuclear vs core collapse (if thermonuclear first X-ray emitting thermonuclear supernova - **2025cof, 2019ehk, 2021gno**)
- Binarity - spiral CSM structure, asymmetry, complex CSM

# Summary

- Explosion

↓ Internal energy driven

- Flash Ionization

↓ Radiation driven,  
photons at  $c$

- CSI Onset

↓ Shock-driven, matter  
at  $10^4 \text{km/s}$

- Long-term Interaction

Sustained shock  
power

- Earliest signature of CSM - Flash ionization

- Sets the inner boundary condition - independent of shock st

- Purely radiative phenomenon

- Samples months - years before explosion

- Circumstellar interaction as a fossil record of stellar death

- mass-loss rates - decades to centuries before explosion

- eruption timescales

- binarity

- pre-SN instability mechanisms

# Summary - Observational regime

- Earliest signature of CSM - Flash ionization
  - Alert latency
  - Robotic spectroscopy
  - Classification pipelines
- Circumstellar interaction as a fossil record of stellar death
  - Early optical
  - Soft to hard X-ray
  - Early mm, early to late cm radio
  - Cadence matters more than depth
  - Optical X-ray, radio synergies
- **Early spectra → final instability in the progenitor**
- **Study lasting weeks–months → eruptive mass loss**
- **CS interaction for years → binary interaction history**

# Summary - Observational regime

- Hydrogen rich supernovae - moderate long lasting CSM (Red supergiants!)
- Type IIb supernovae - common late time rebrightenings (binarity important)
- Interacting hydrogen rich supernovae - enhanced mass loss centuries before explosion (LBV kind mass eruptions)
- Interacting hydrogen poor supernovae - enhanced mass loss years before explosion (merger scenario?)
- Core-collapse CaSTs - enhanced mass loss months before explosion (weak explosion with enhanced mass loss just before death)
- **Fine tuned strategies for different class of supernovae**
