

**Three Preludes on a
Theme of Magnetars**

Last Week!

Todd Thompson
Ohio State University

Tejas Prasanna, Jakub Cehula, Ani Patel

M. Coleman, P. Chang, N. Bucciantini, A. ud-Doula, B. Metzger, E. Quataert

The background is a dark, deep blue gradient, transitioning from a slightly lighter blue at the top to a darker blue at the bottom. It is filled with numerous small, white and light blue specks, resembling a starry night sky or a digital particle effect. There are also a few larger, brighter spots with a soft glow, particularly in the lower right quadrant.

Advertisement #1.

ASAS SN

Stanek, Kochanek, Shappee + Since circa 2015

5 mounts: Chile (2), Hawaii, Texas, South Africa

4 telescopes/mount; 14cm; 2k×2k CCDs

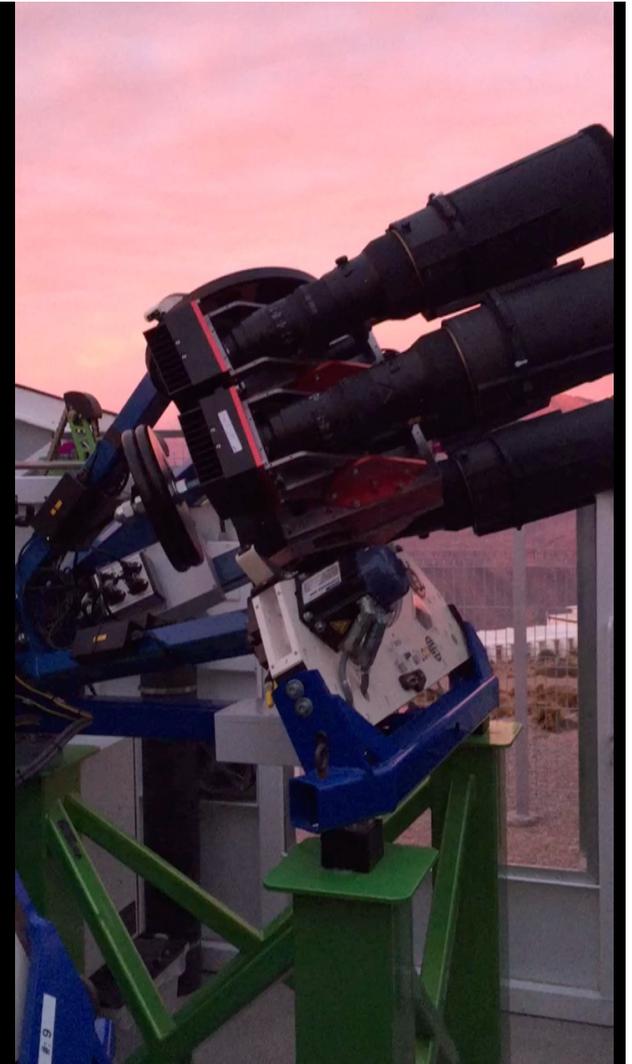

4.5° × 4.5° field-of-view, 8" pixel scale

g-band filters; depth of 18.5 mag in 90 s

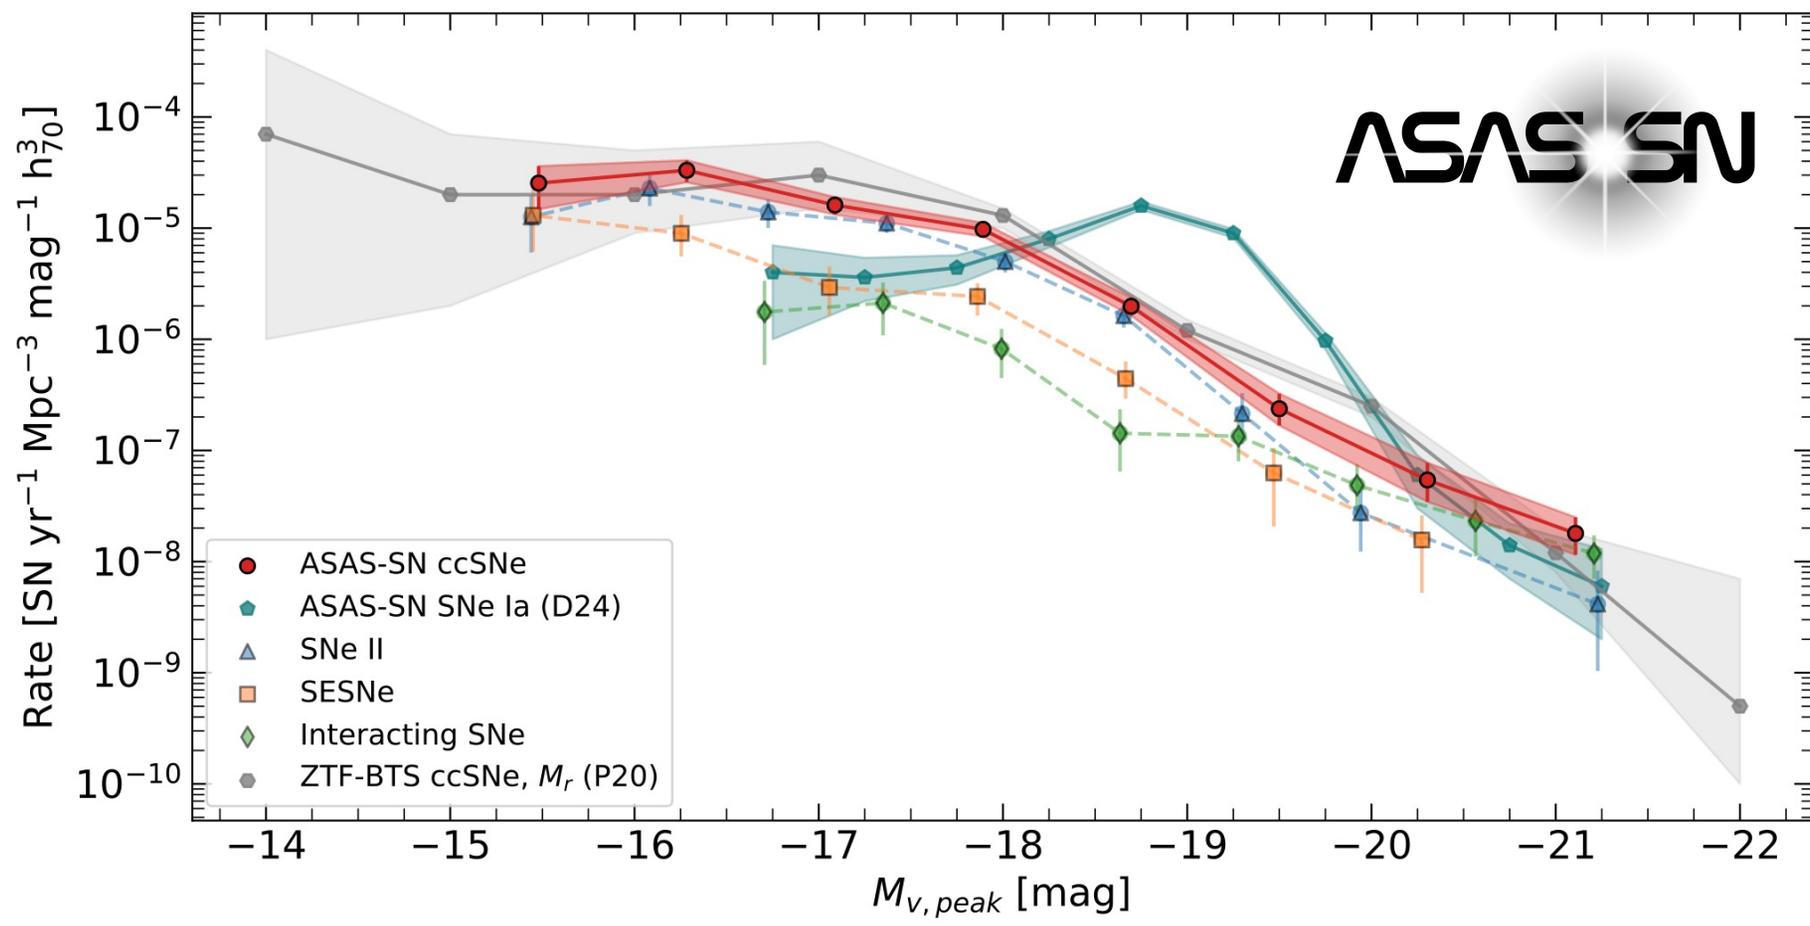

≈ 6500 images & 40,000 square degrees/night

Many Discoveries:

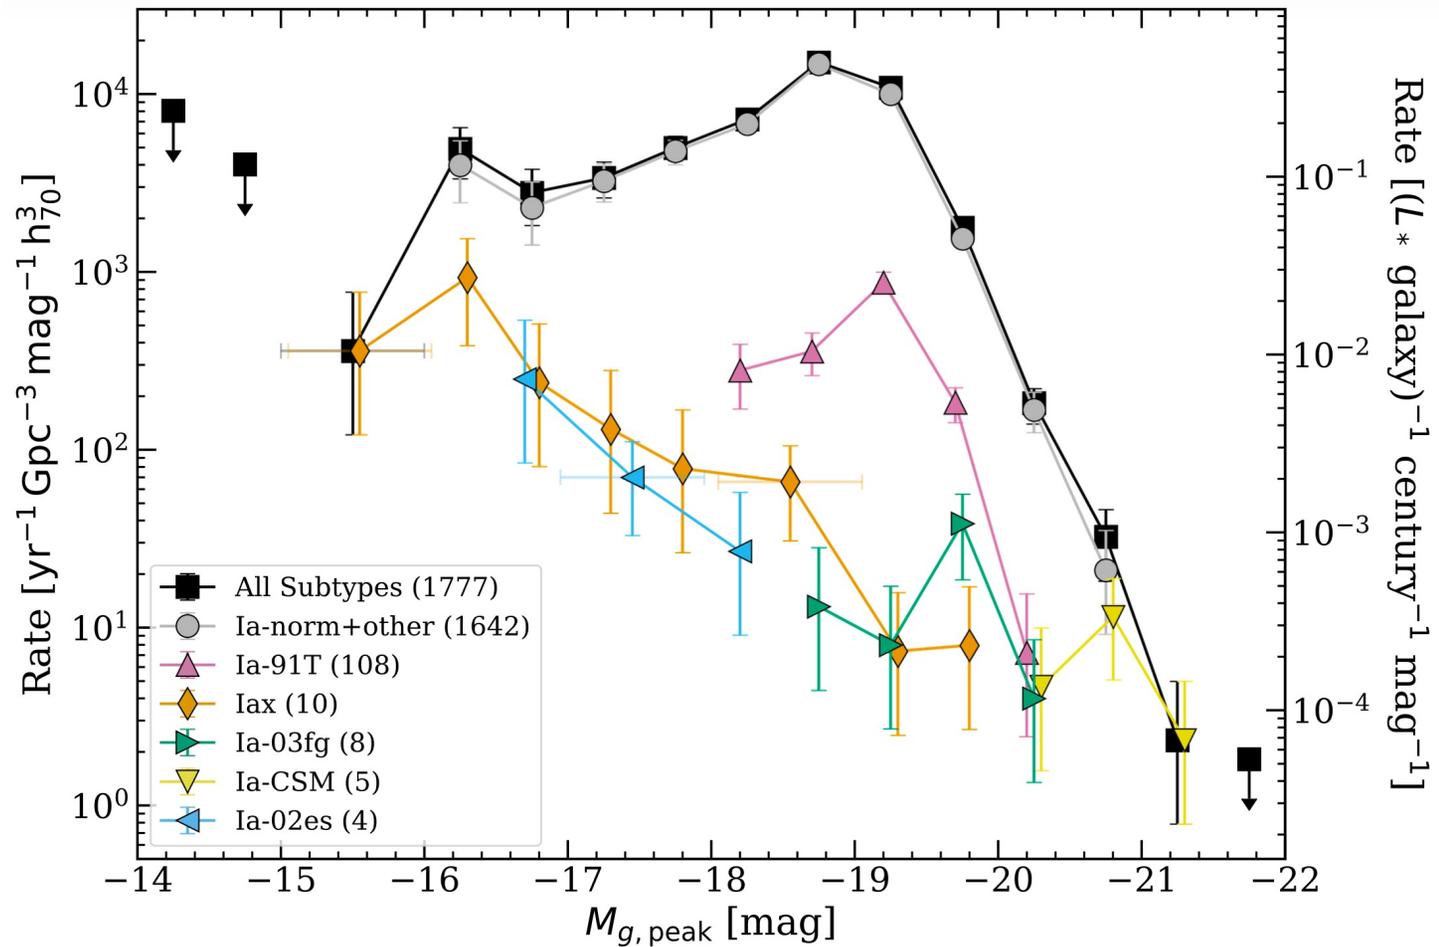

ASSASN14li, 14ae, 15oi; 15lh; 14ko; heartbeats,
binaries, variables; **Sky Patrol** ... SN Rates ...

Pessi et al. (2025): Type II Rates and Luminosity Functions

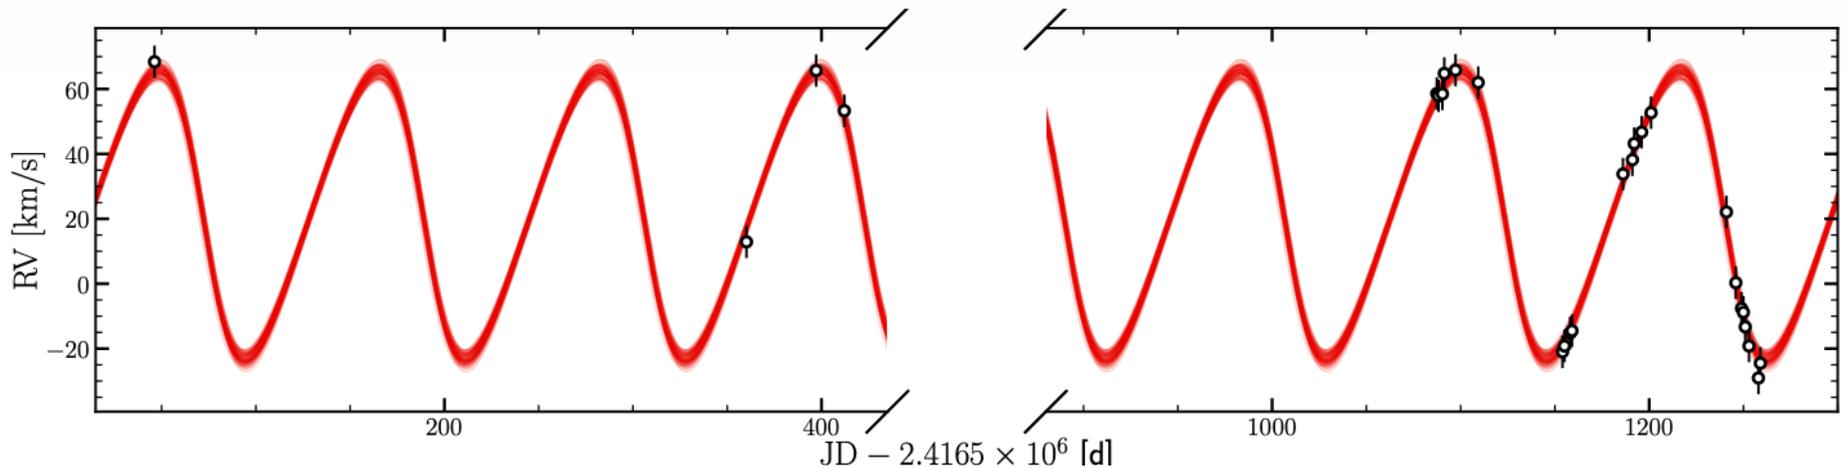

Desai et al. (2026): Type Ia Rates and Luminosity Functions

The background is a dark blue gradient, transitioning from a deeper blue at the top to a lighter, more vibrant blue at the bottom. It is filled with numerous small, white and light blue specks, resembling a starry night sky or a digital particle effect. A few larger, brighter spots are visible, particularly in the lower right quadrant, which appear to be stylized stars or light sources with soft halos.

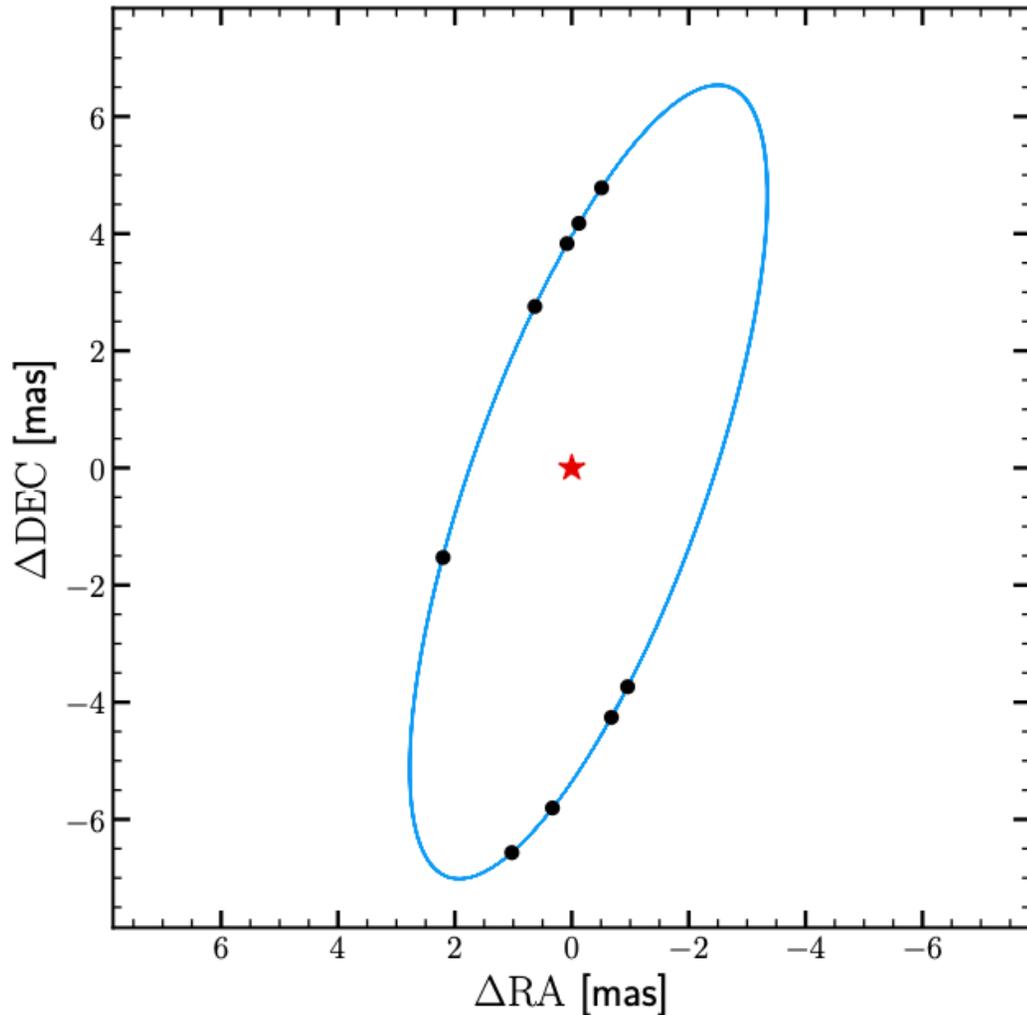

Advertisement #2.

Stellar-BH Binary Candidate Kappa Velorum (Markeb, HD 81188, 天社五)

$V = 2.5$ mag. B star $M \sim 10M_{\text{sun}}$. Single-lined spectroscopic binary with large mass function $f(M) = 1.15M_{\text{sun}}$. $P = 117$ days (Curtis 1907).

Trimble & Thorne (1969) suggest possible BH companion.

Rowan, Kraus, Thompson 26

Direct imaging with VLT/ GRAVITY gives astrometric orbit with $\sim \mu\text{as}$ precision.

$$e = 0.176, i = 74.04^\circ$$

Clear detection of the **stellar** secondary: $7\text{-}8 M_{\text{sun}}$.

→ NOT A BH BINARY.

More systems in preparation.

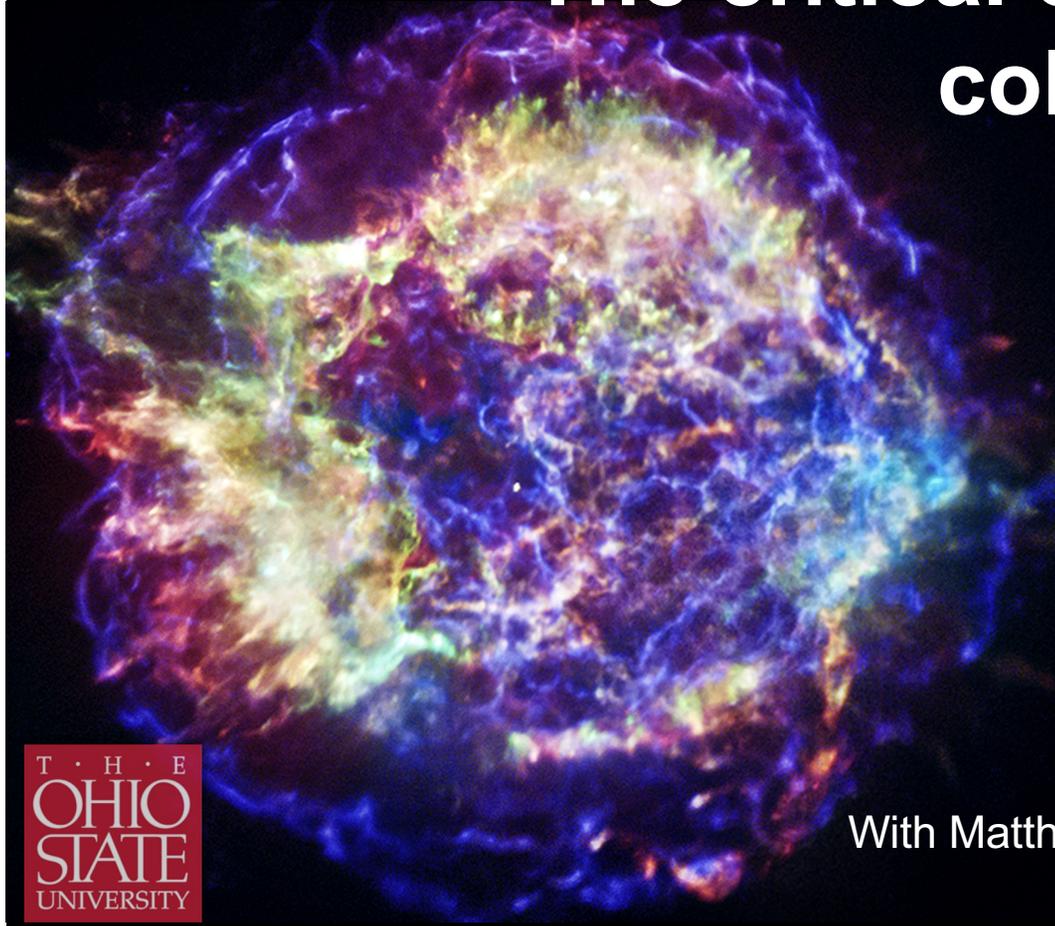

Changing subjects again...

The critical condition for core-collapse supernovae

Todd Thompson
Ohio State University

With Matthias Raives, Ondrej Pejcha, Eric Coughlin

The Question

Why do some core-collapses lead to successful explosions, while others fail?

Why are models always “close” to explosion?

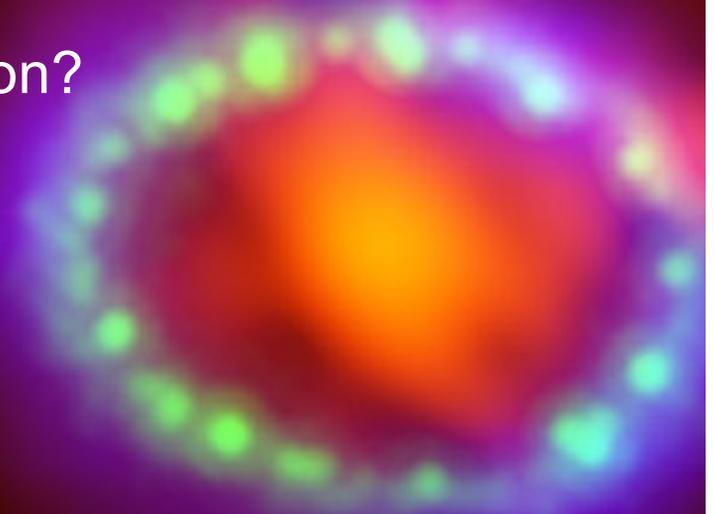

“This model had enough heating, but this other model didn’t.”

→ Physically, why?

The Stakes

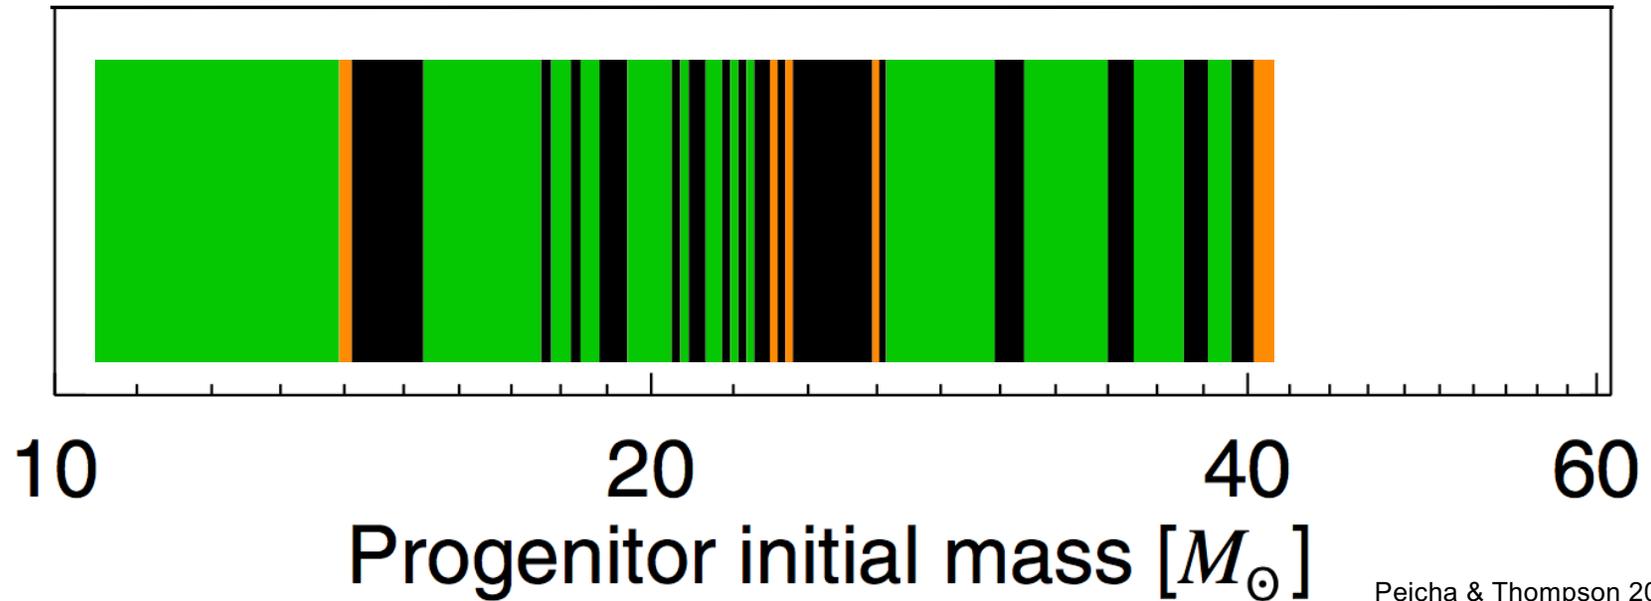

The Oxygen in your air, water, and food comes from here.

All life depends on supernovae succeeding, yet 20-40% fail. Why?

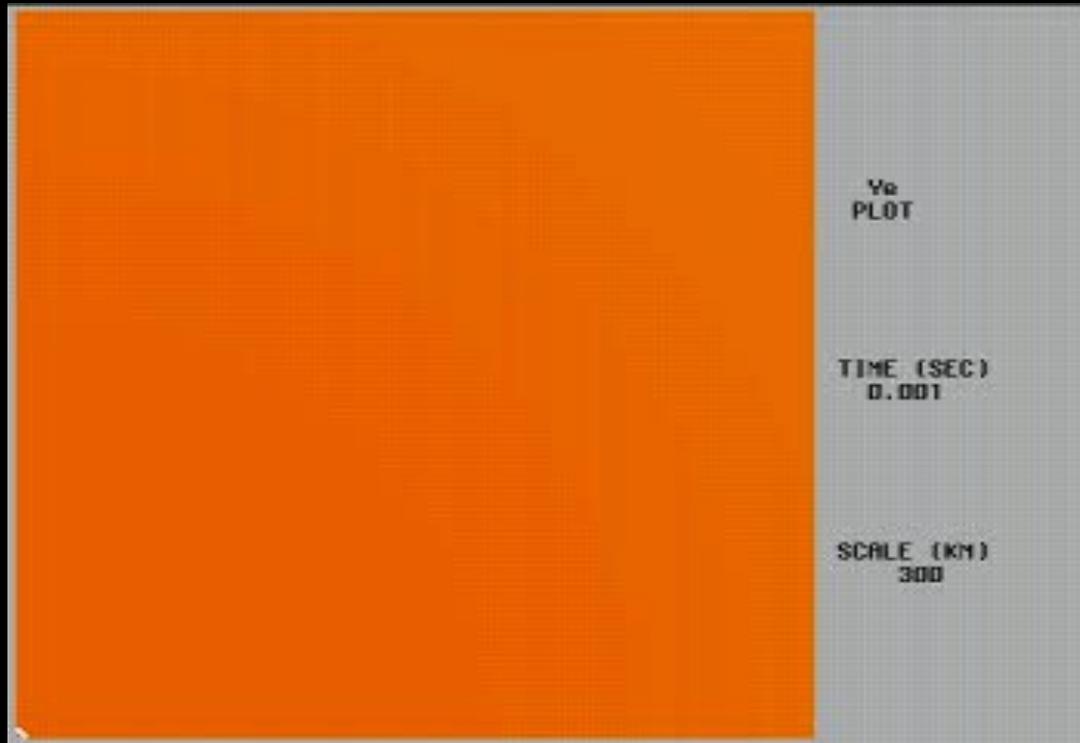

A complicated landscape of outcomes: 25% BHs(?)

■ neutron star ■ significant fallback ■ failed explosion, BH

Many groups find similar results → progenitor structure.

Collapse, Bounce, Stall, Wind-Driven Explosion, Cooling

300 km

Electrons combine
with protons to make
a neutron star:

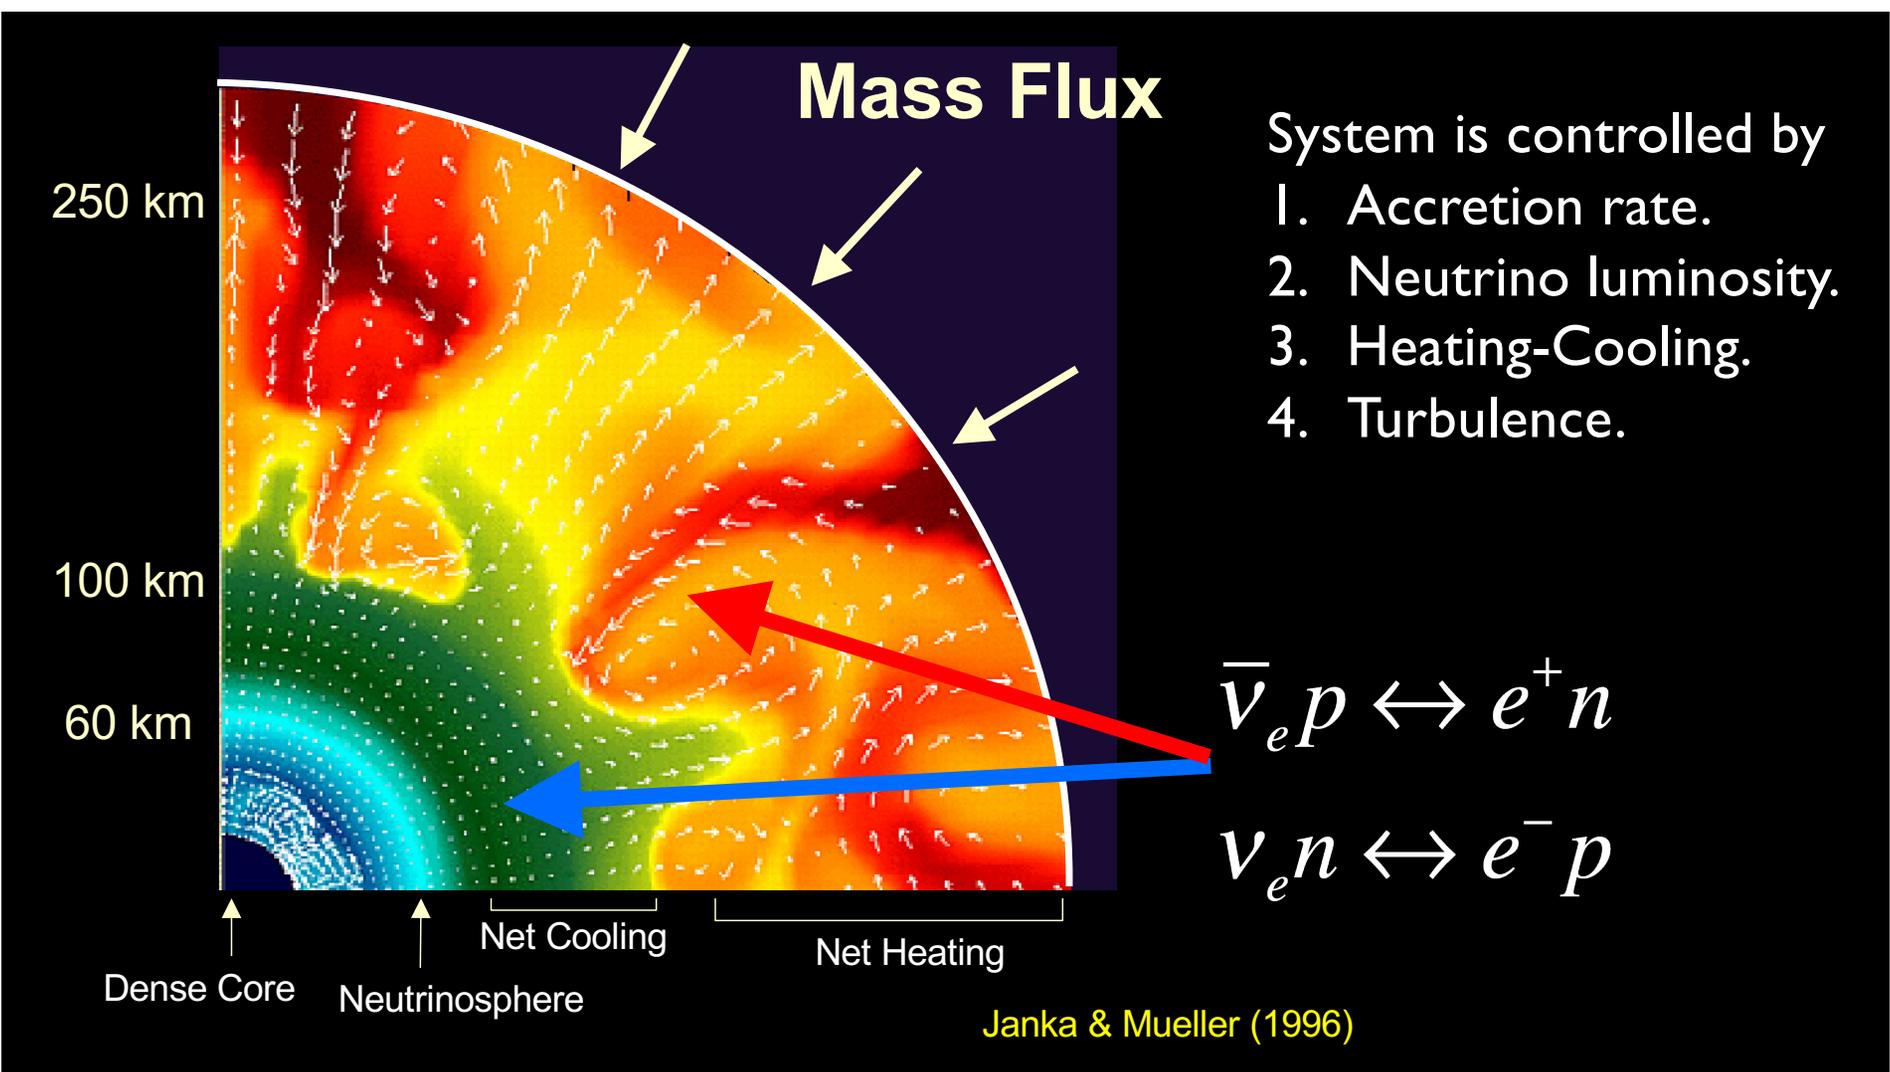

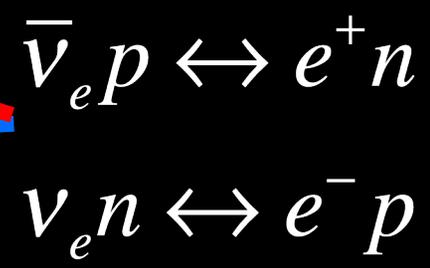

Escaping neutrinos
interact with infalling
matter, heating it:

Explosion in ~ 1 second,
or a BH will form.

Mass Flux

- System is controlled by
1. Accretion rate.
 2. Neutrino luminosity.
 3. Heating-Cooling.
 4. Turbulence.

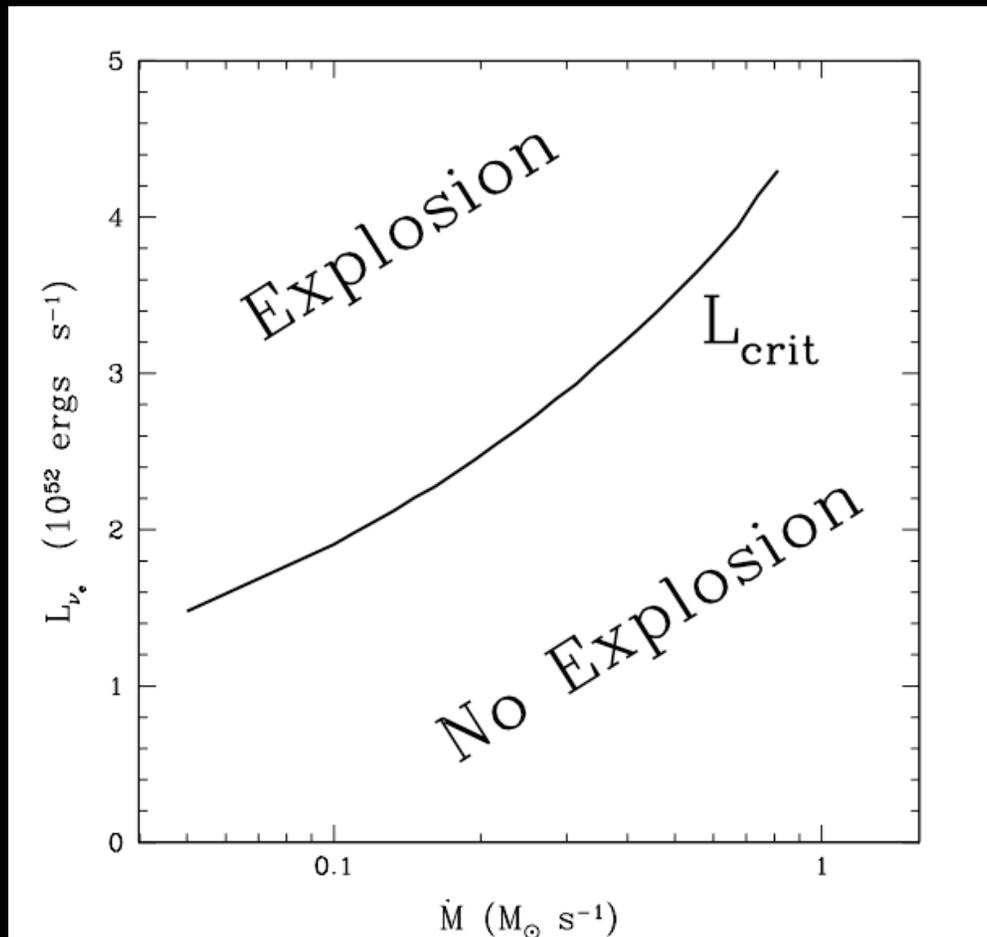

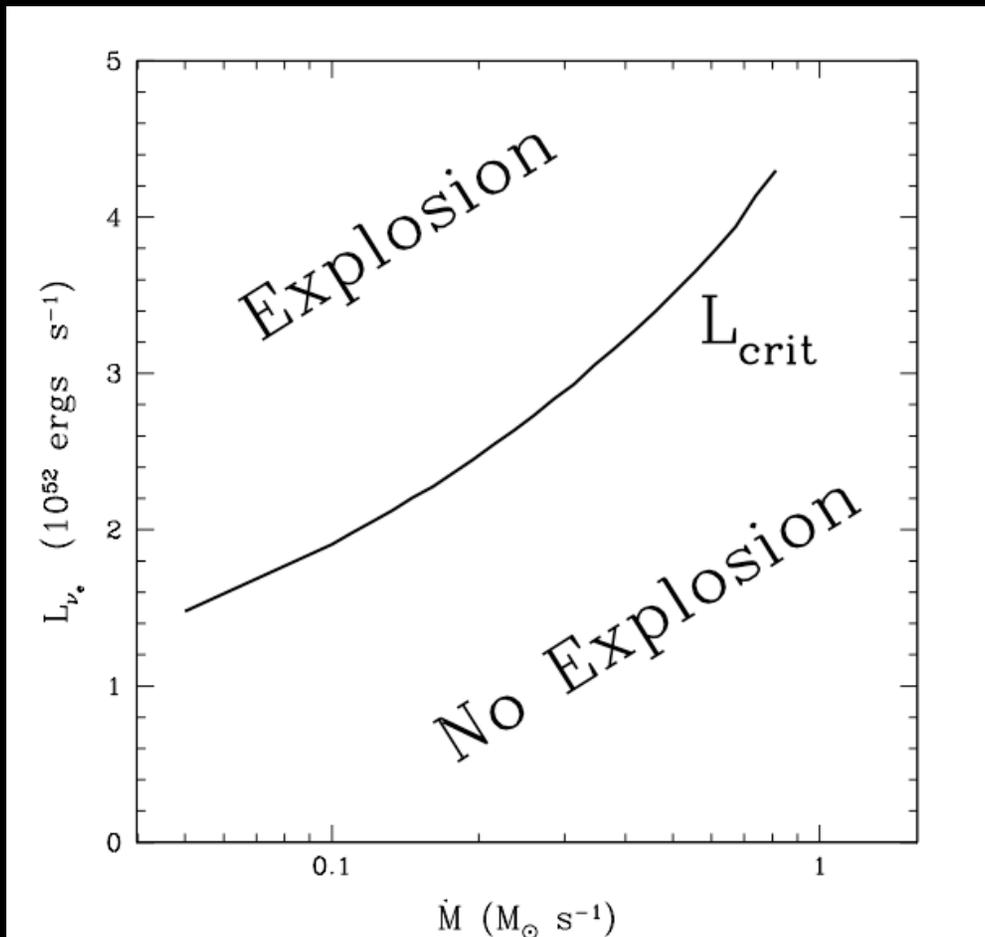

Critical Luminosity

At a given mass accretion rate, there is a critical luminosity above which no accretion solutions.

Burrows & Goshy (1993)
Yamasaki & Yamada (2005, 2006, 2007)
Pejcha & Thompson (2012, 2015)
Raives+(2018,2021)
Pochik & Thompson (2025)
Many additional works...

→ See recent review by Maltsev+(2025)

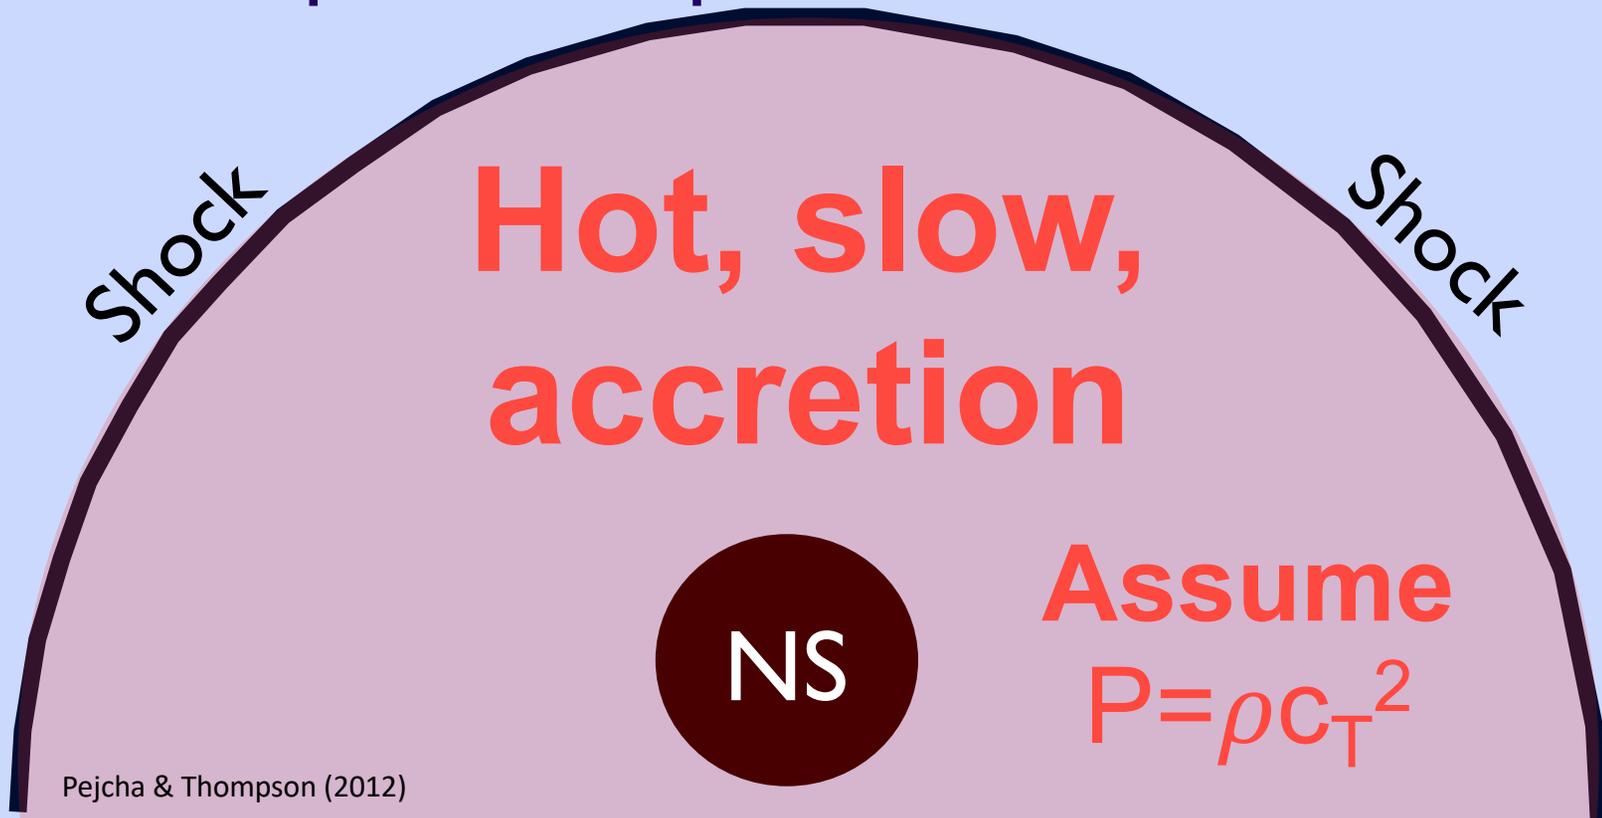

“Model X did not explode! It must have had insufficient neutrino heating. $L < L_{crit}$.”

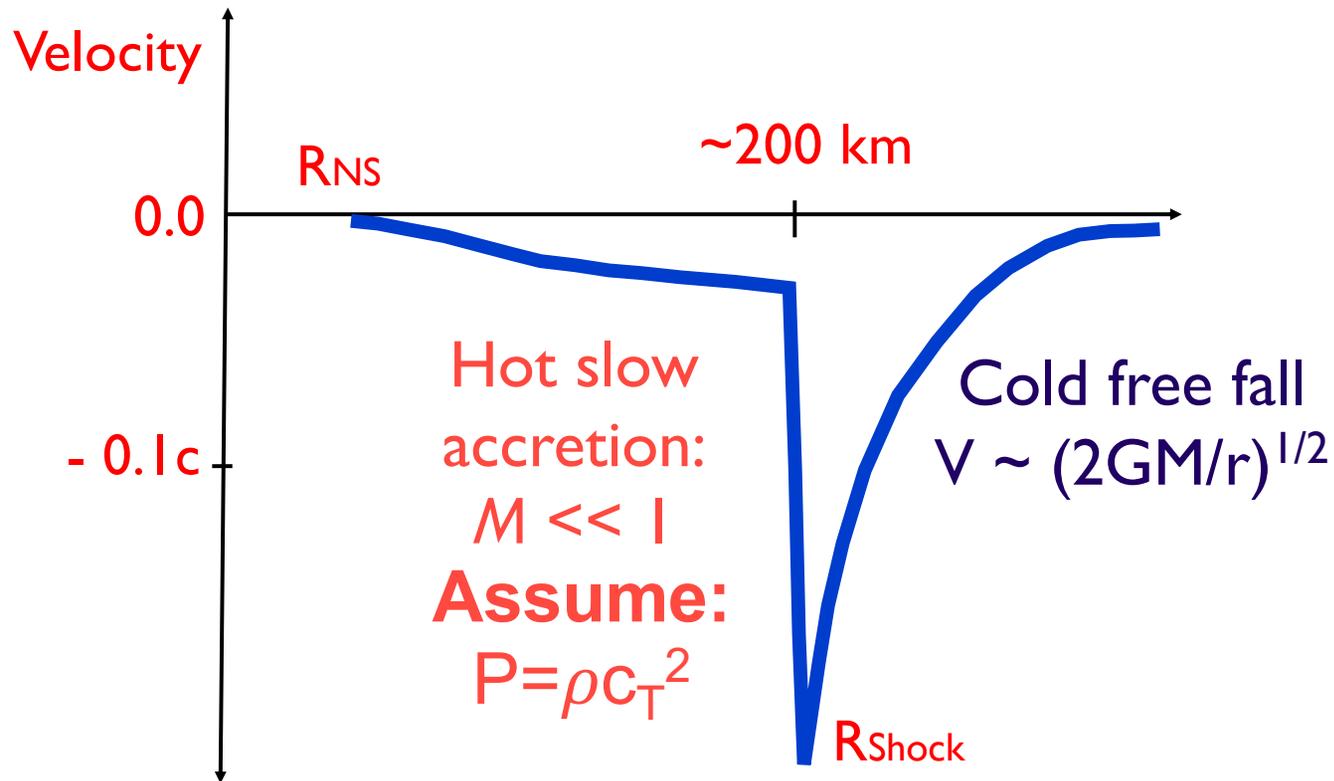

“Model Y explodes! It must have had sufficient neutrino heating. $L > L_{crit}$. Perhaps because of rapid change in \dot{M} .”

BUT, what is the physics of L_{crit} ?

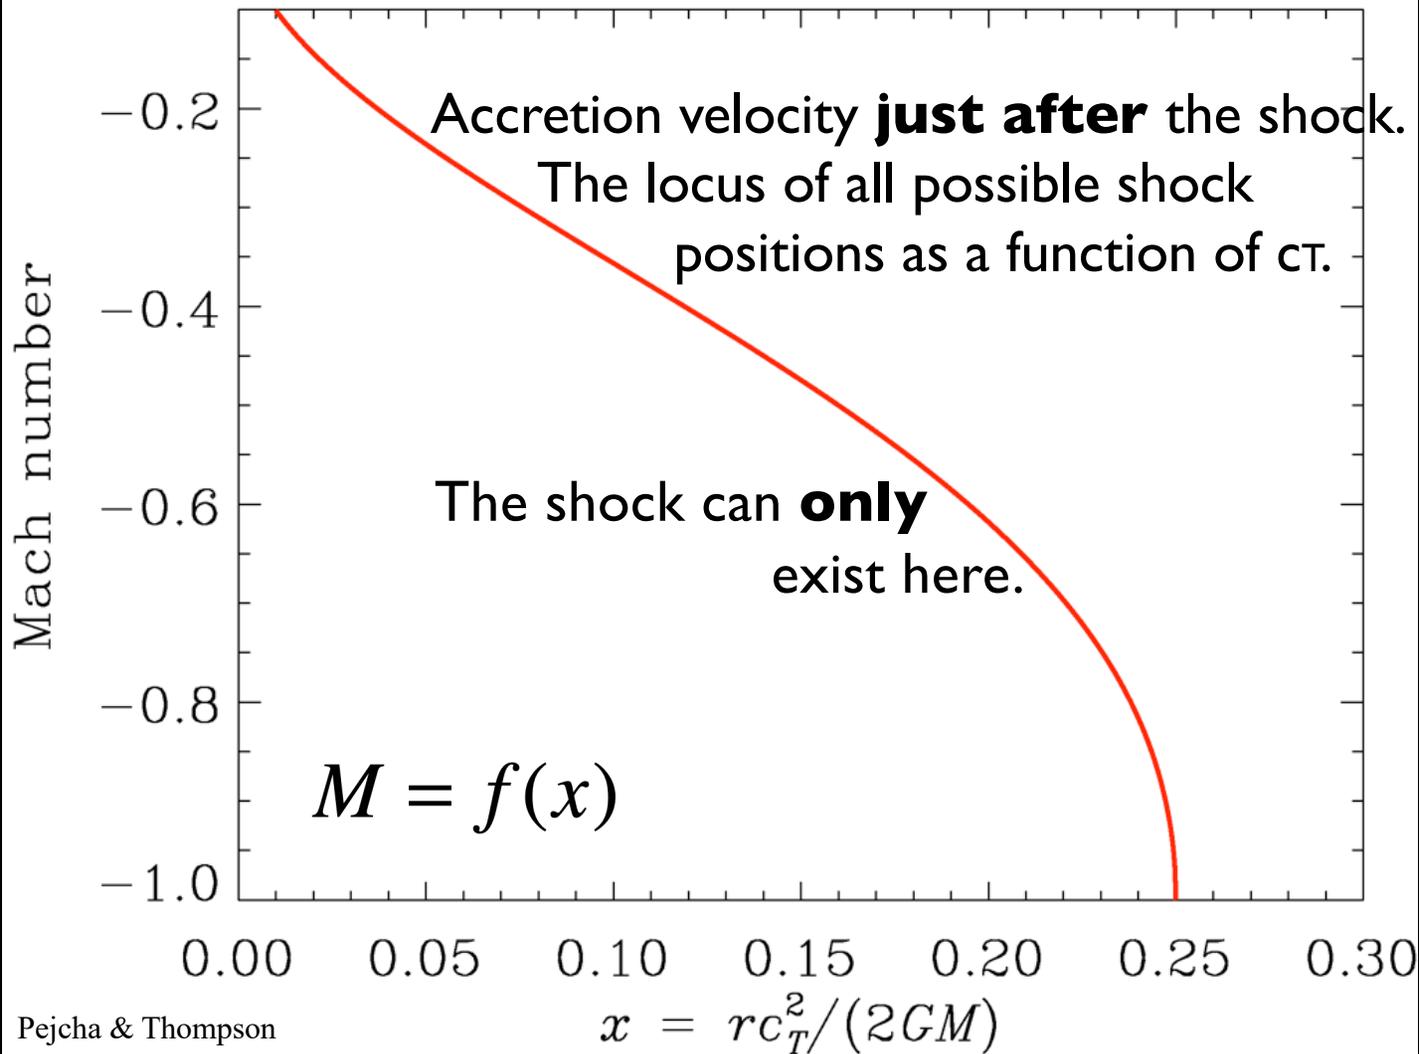

A radical approximation:

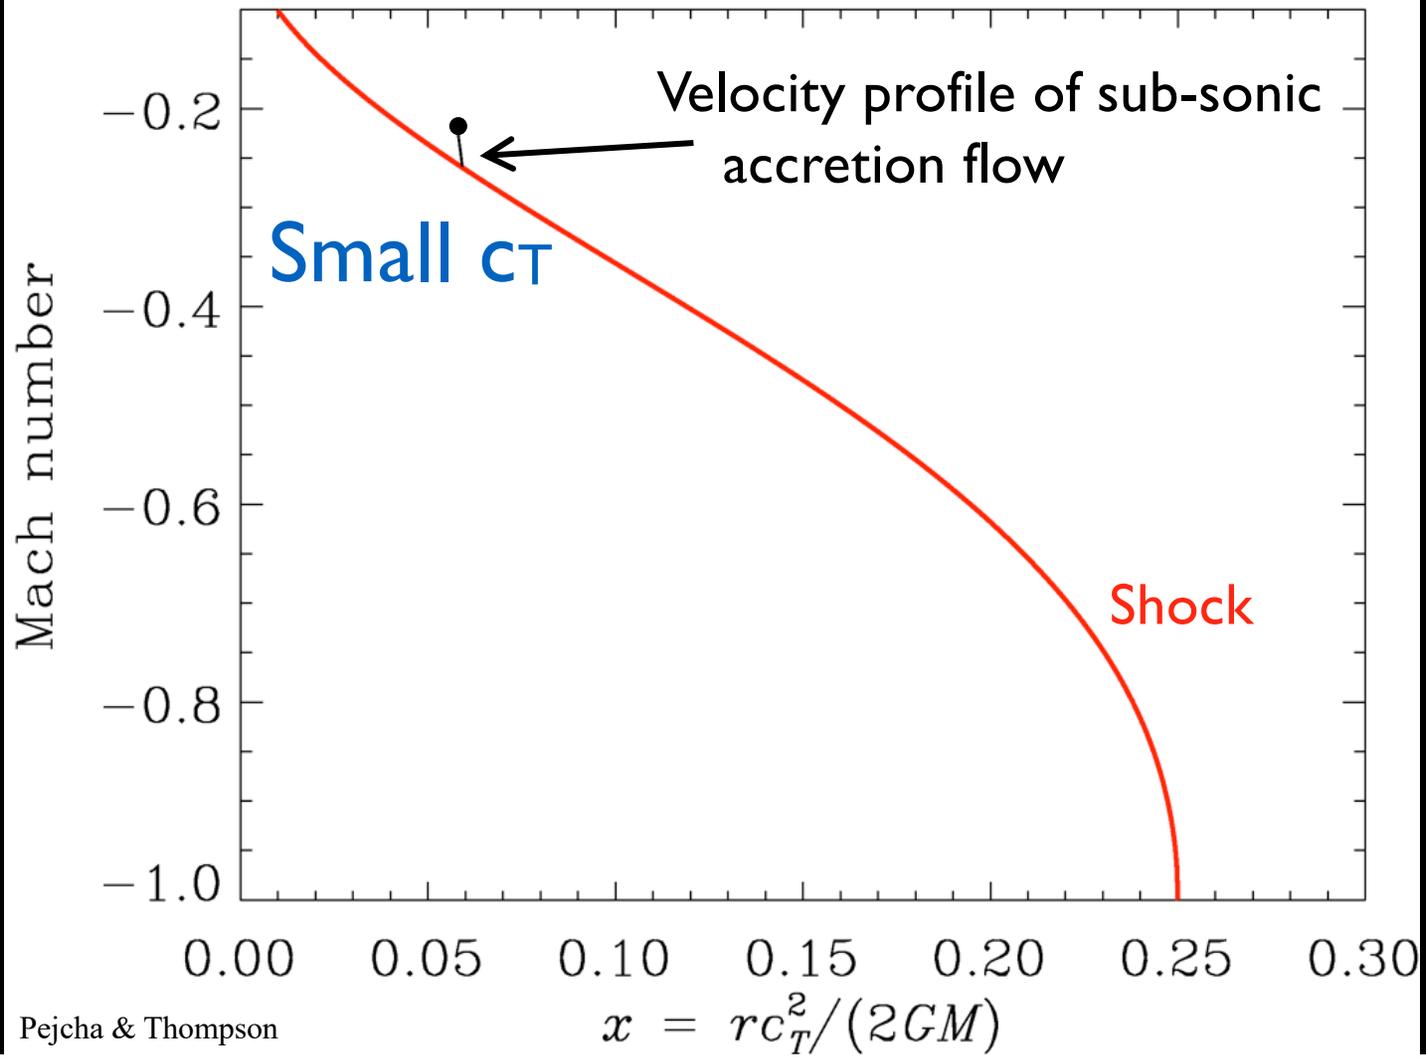

Cold supersonic pressure-less free fall

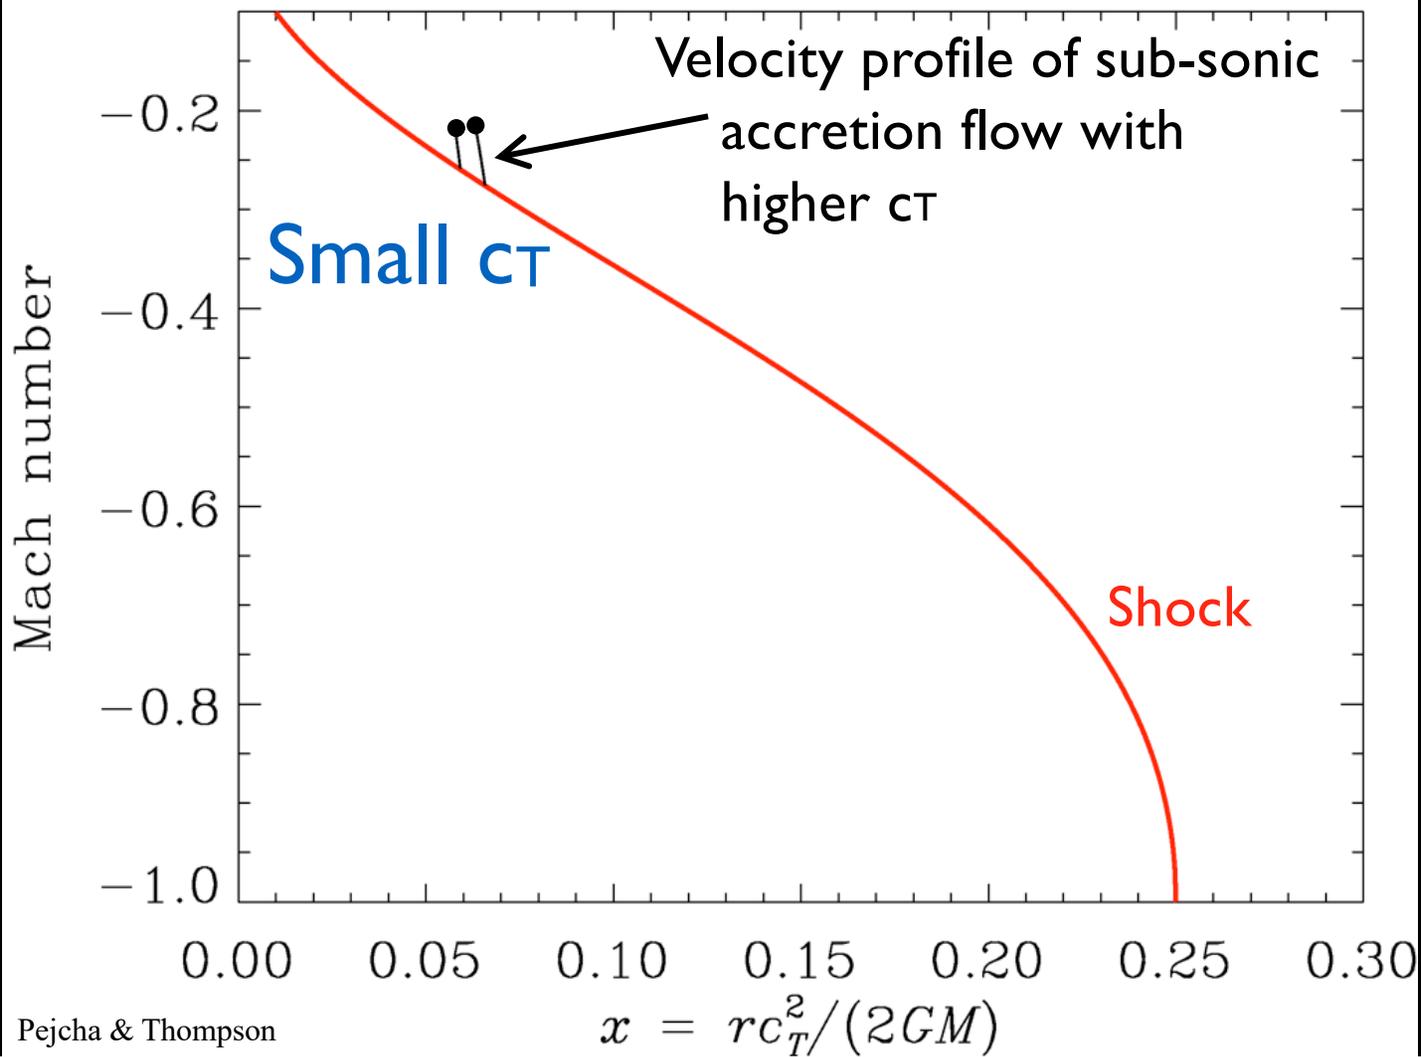

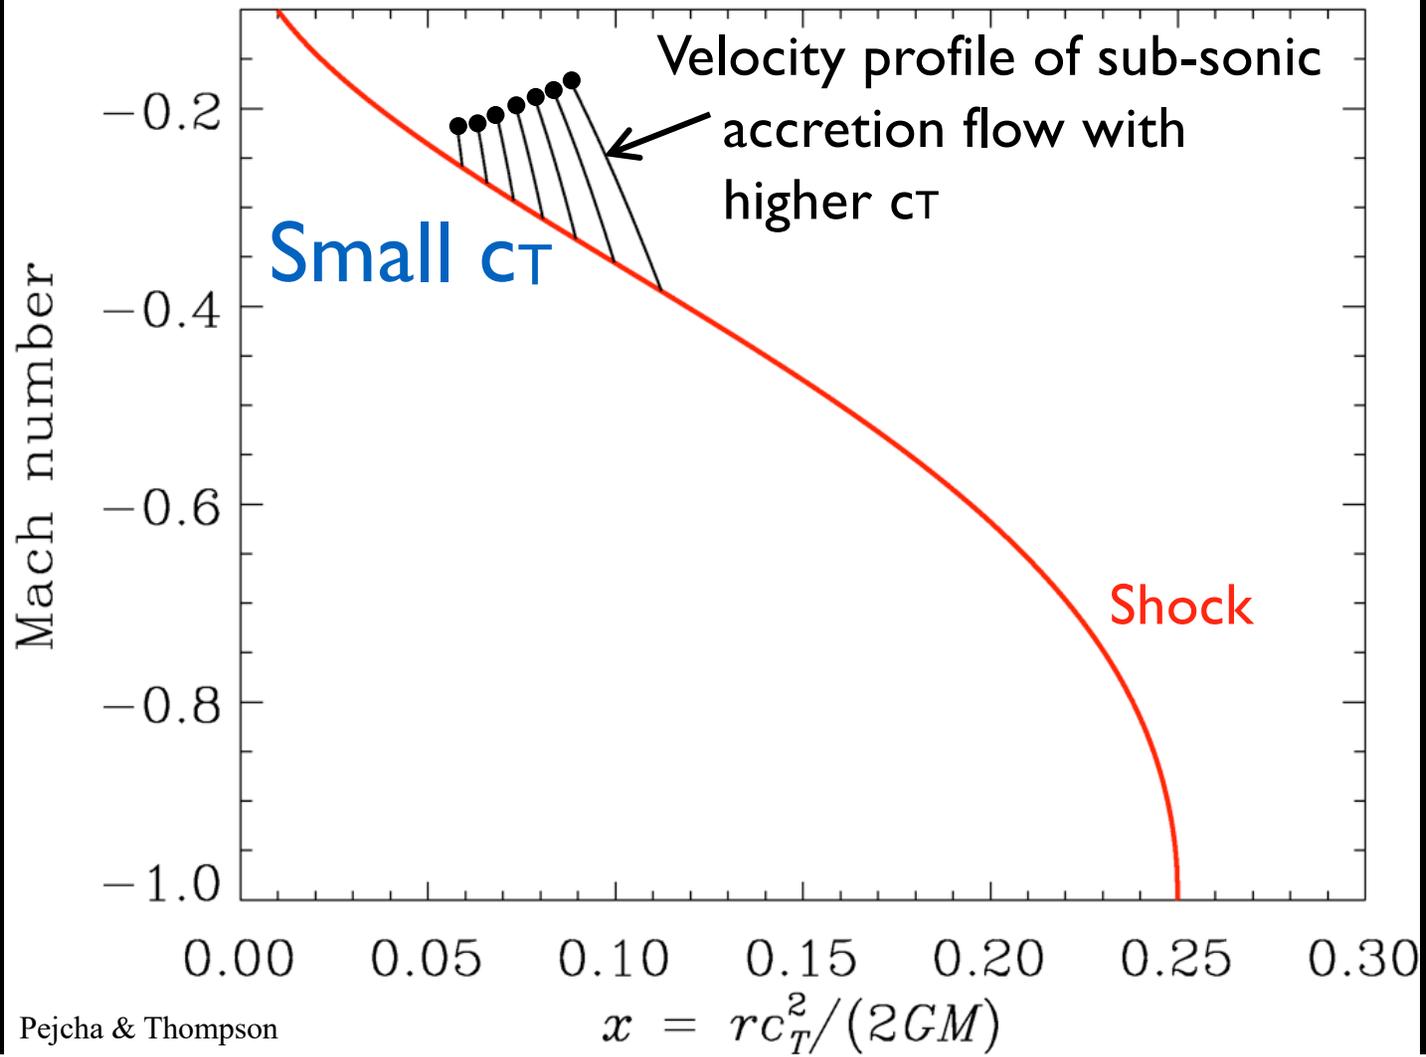

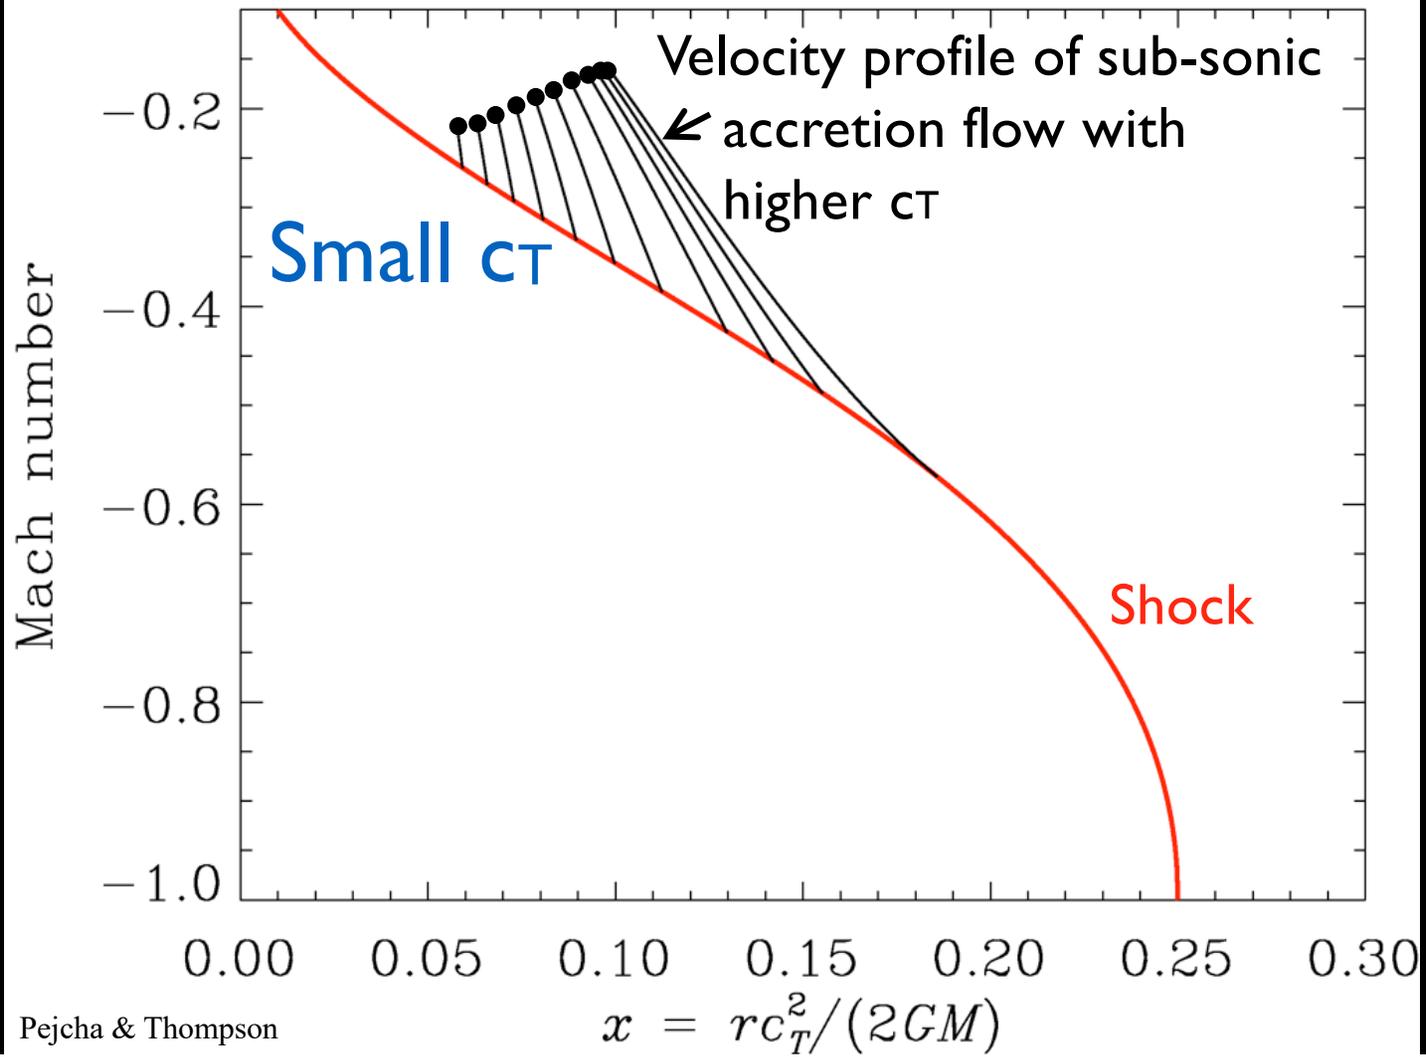

Write down Euler equations for steady flow with shock boundary conditions for given accretion rate.

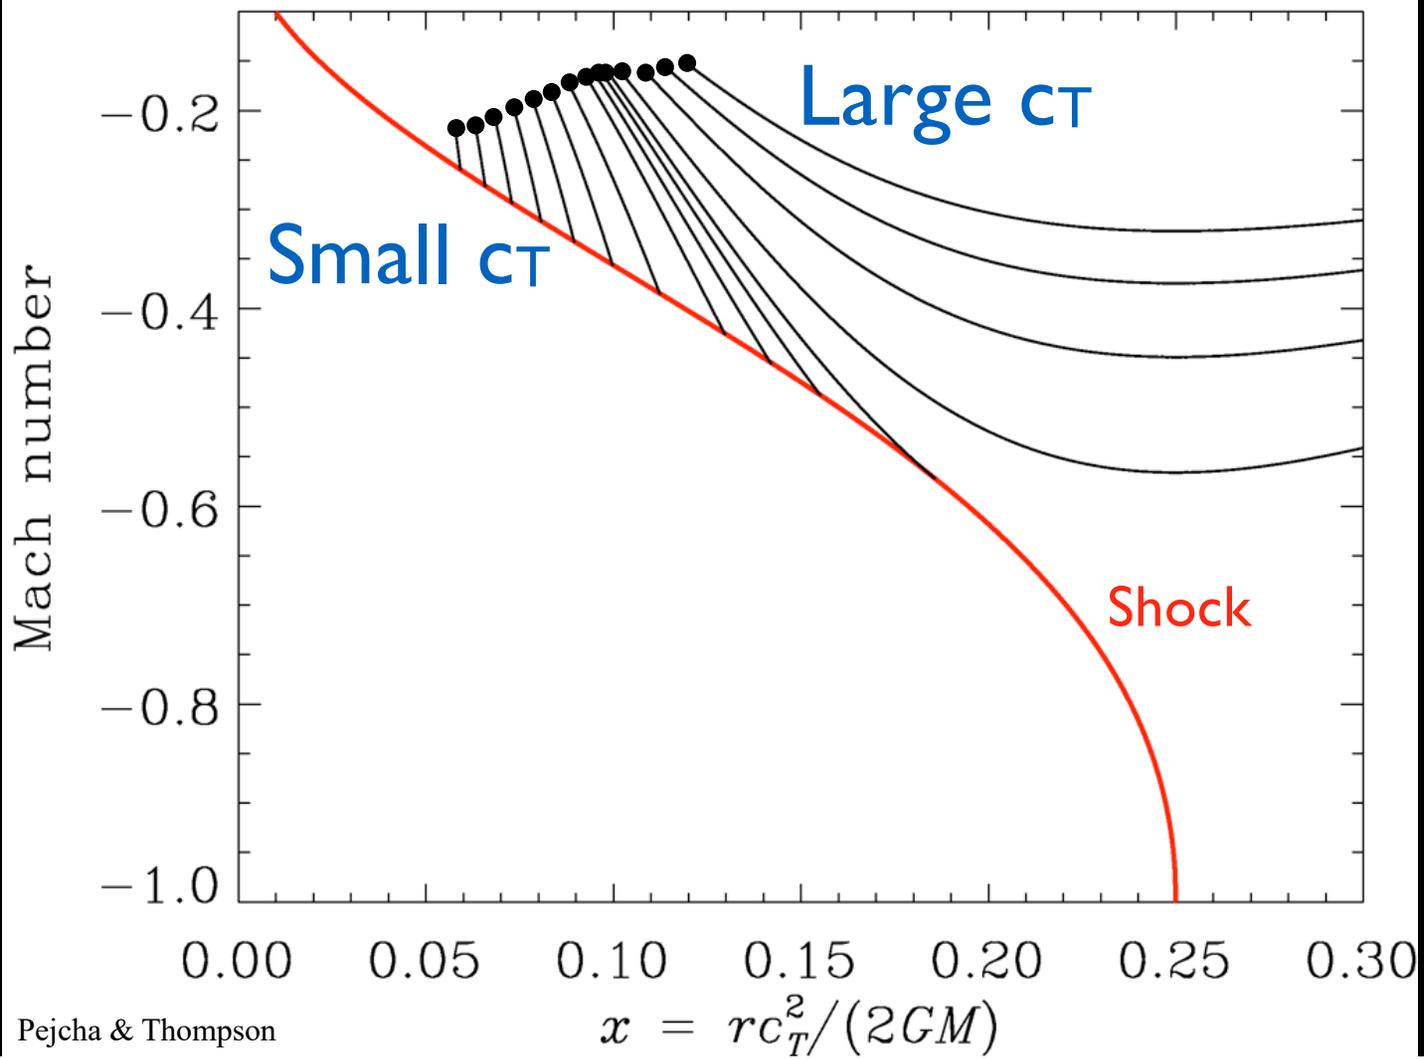

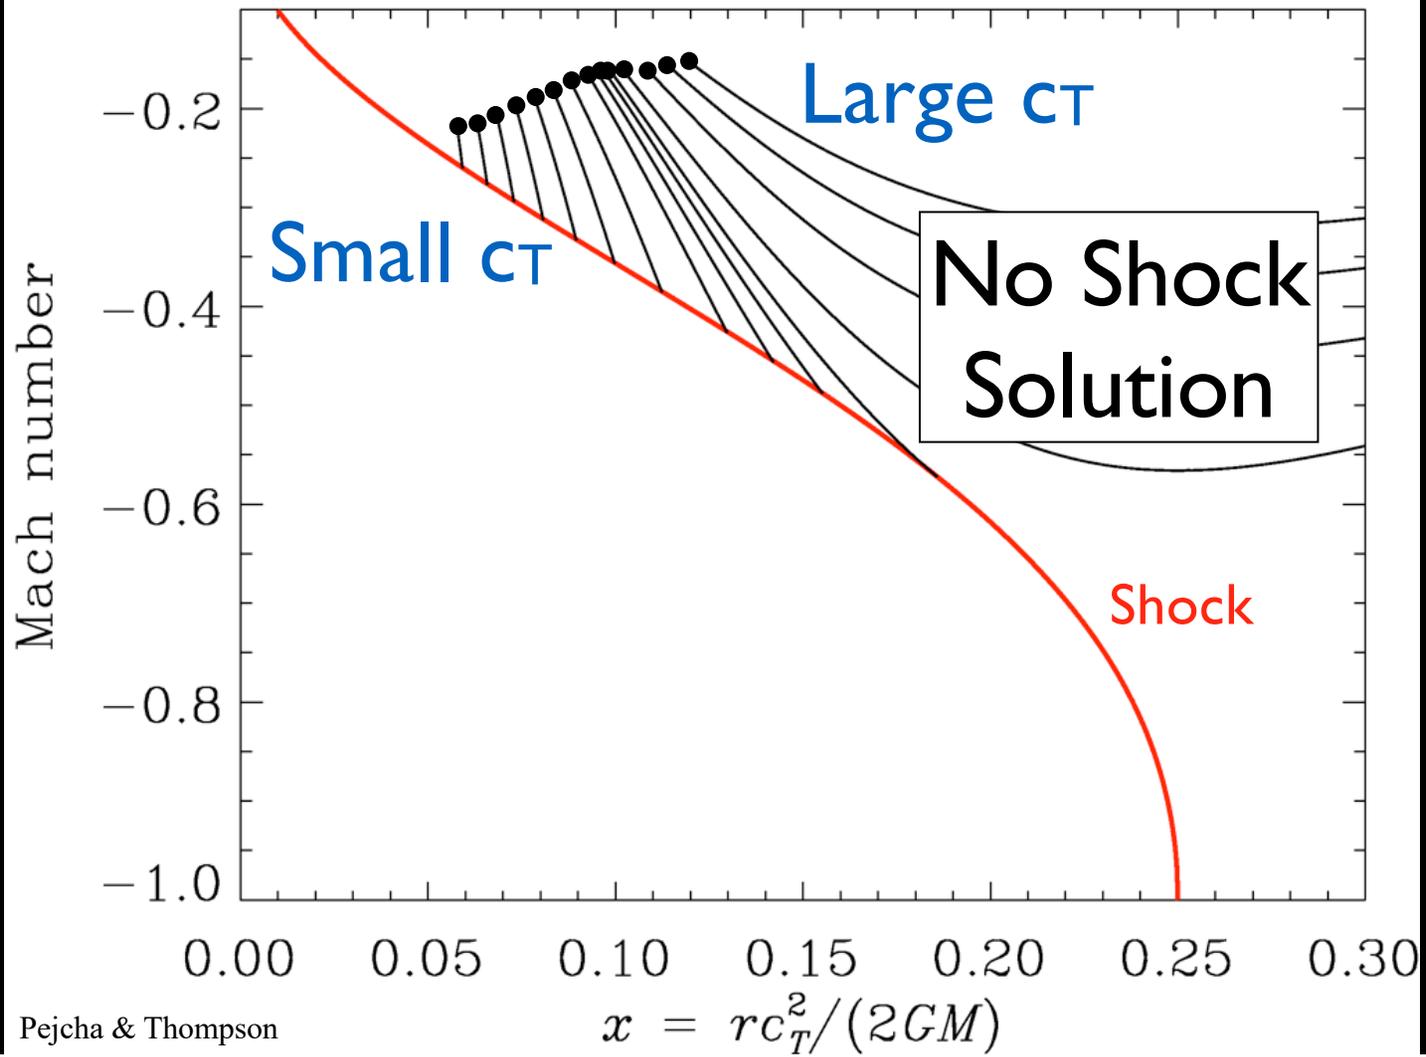

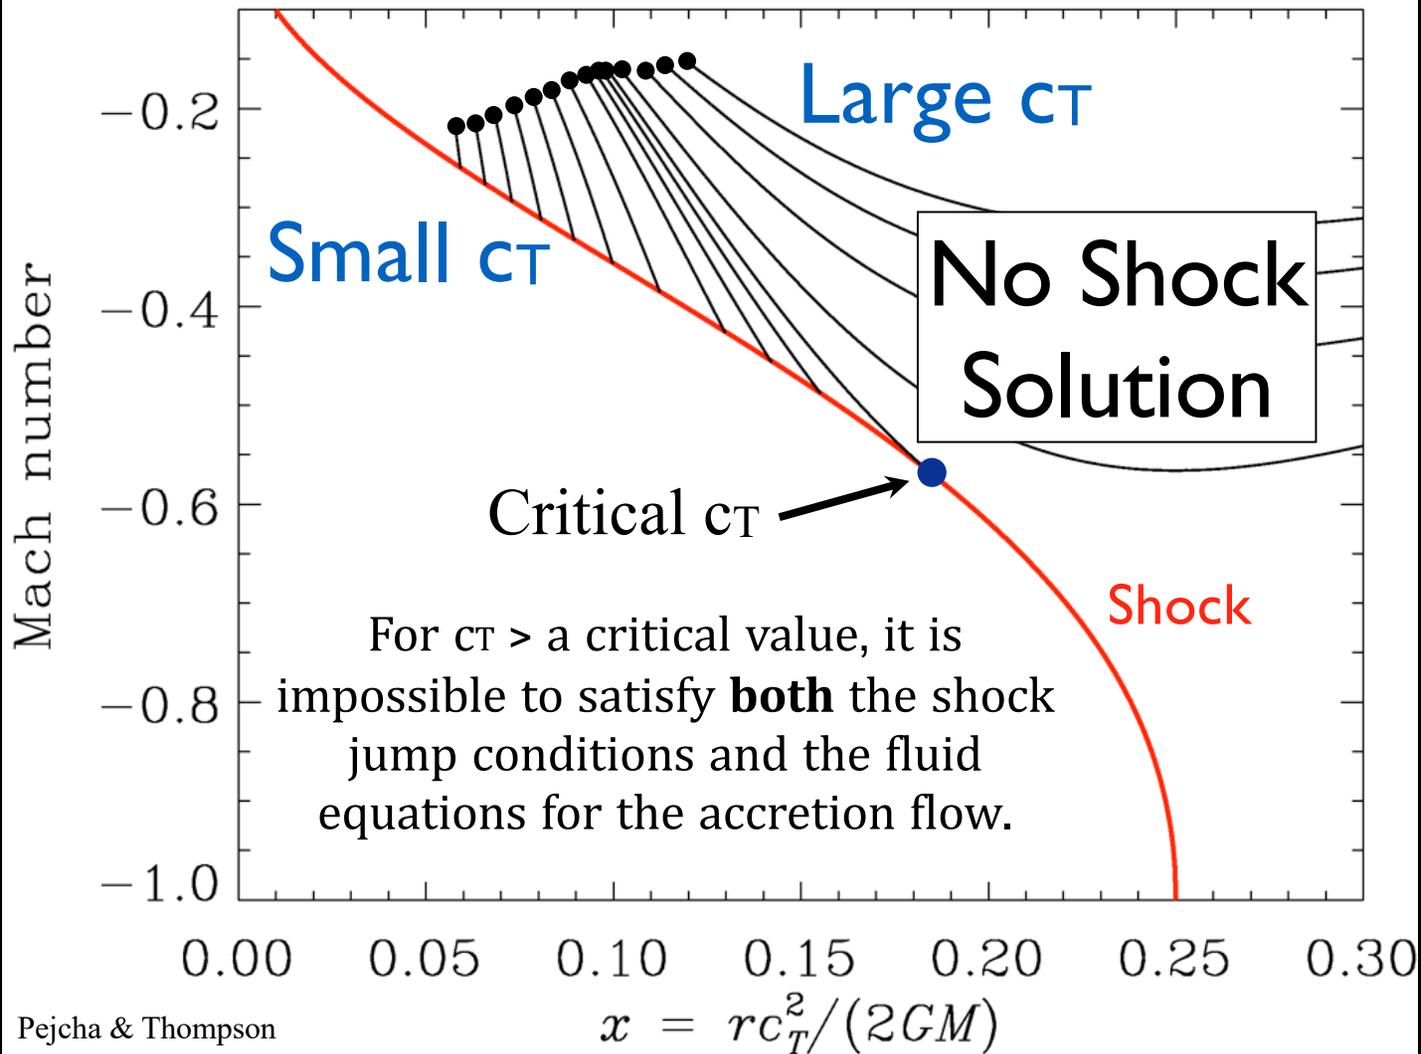

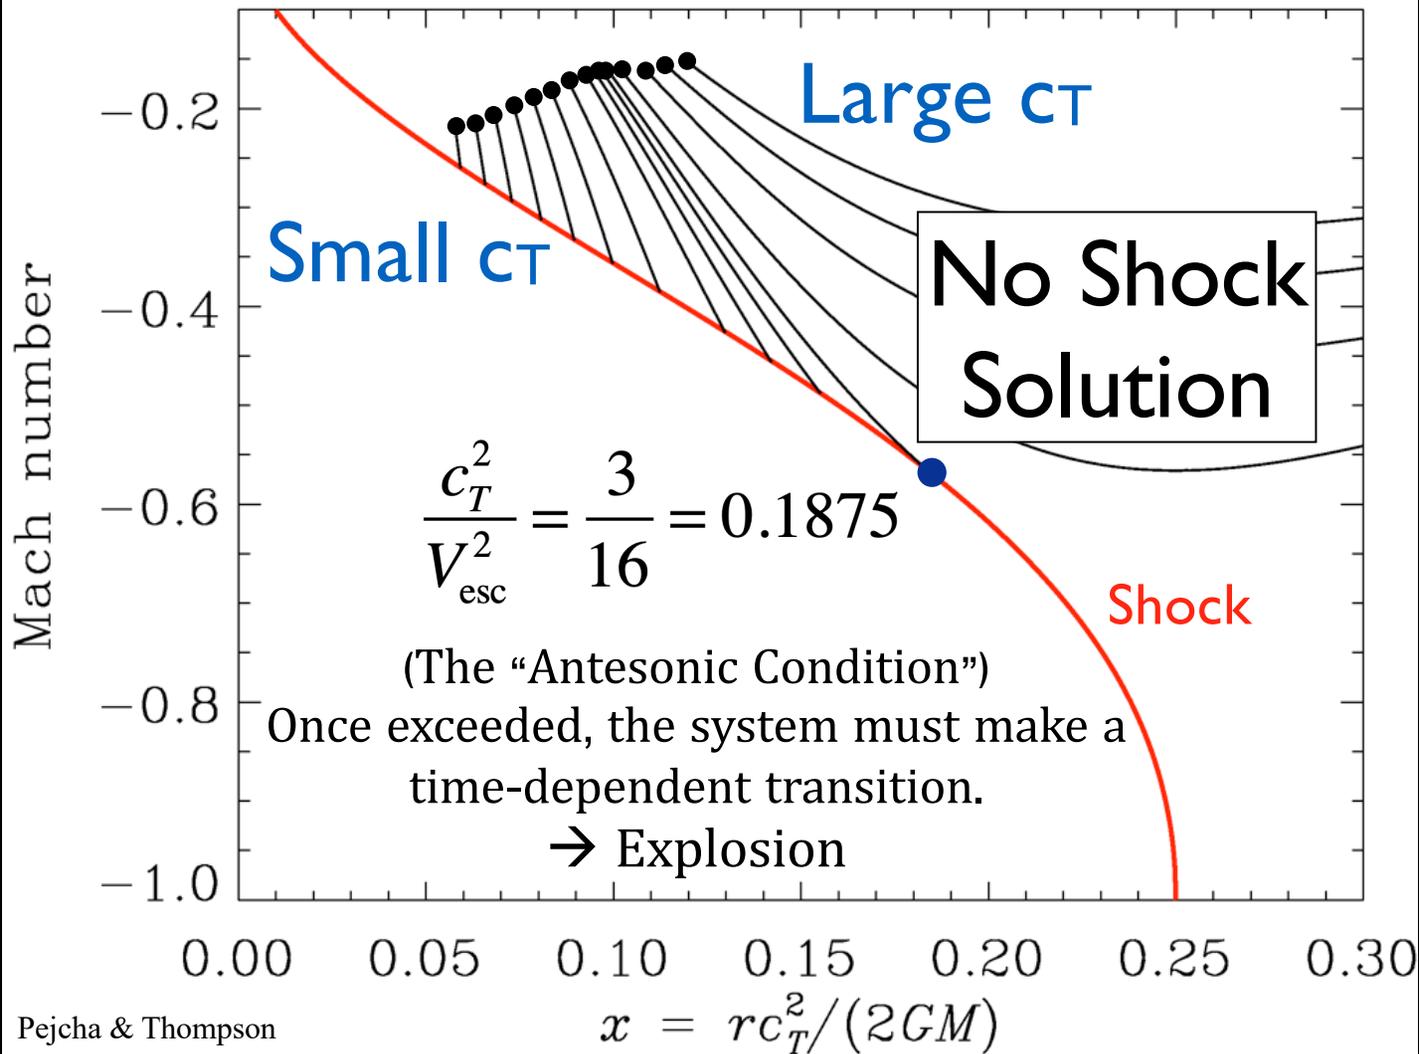

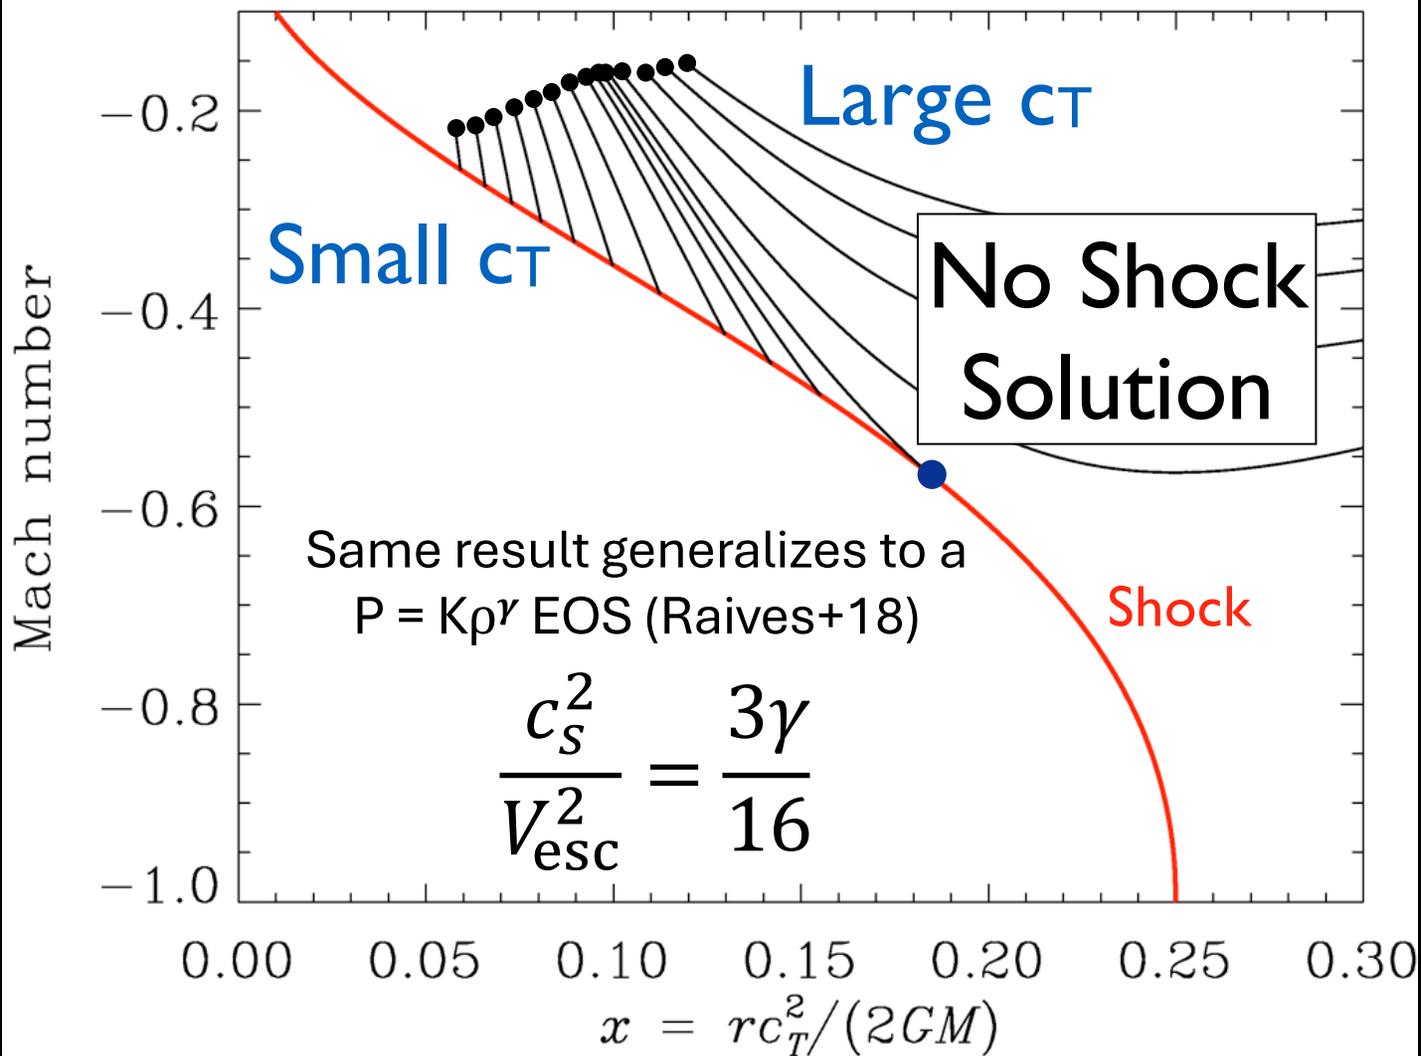

Pejcha & Thompson

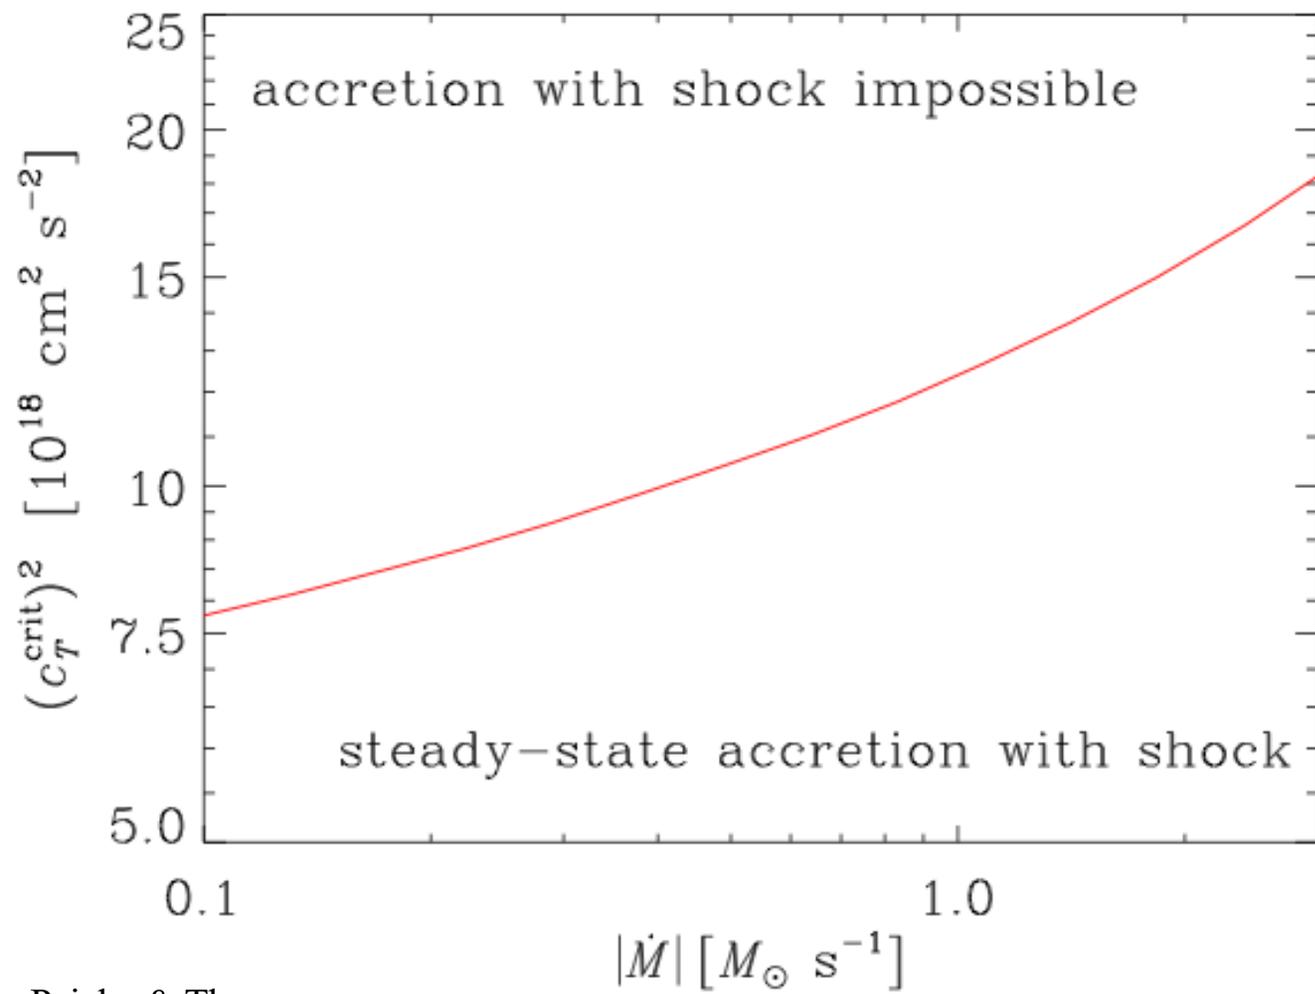

Pejcha & Thompson

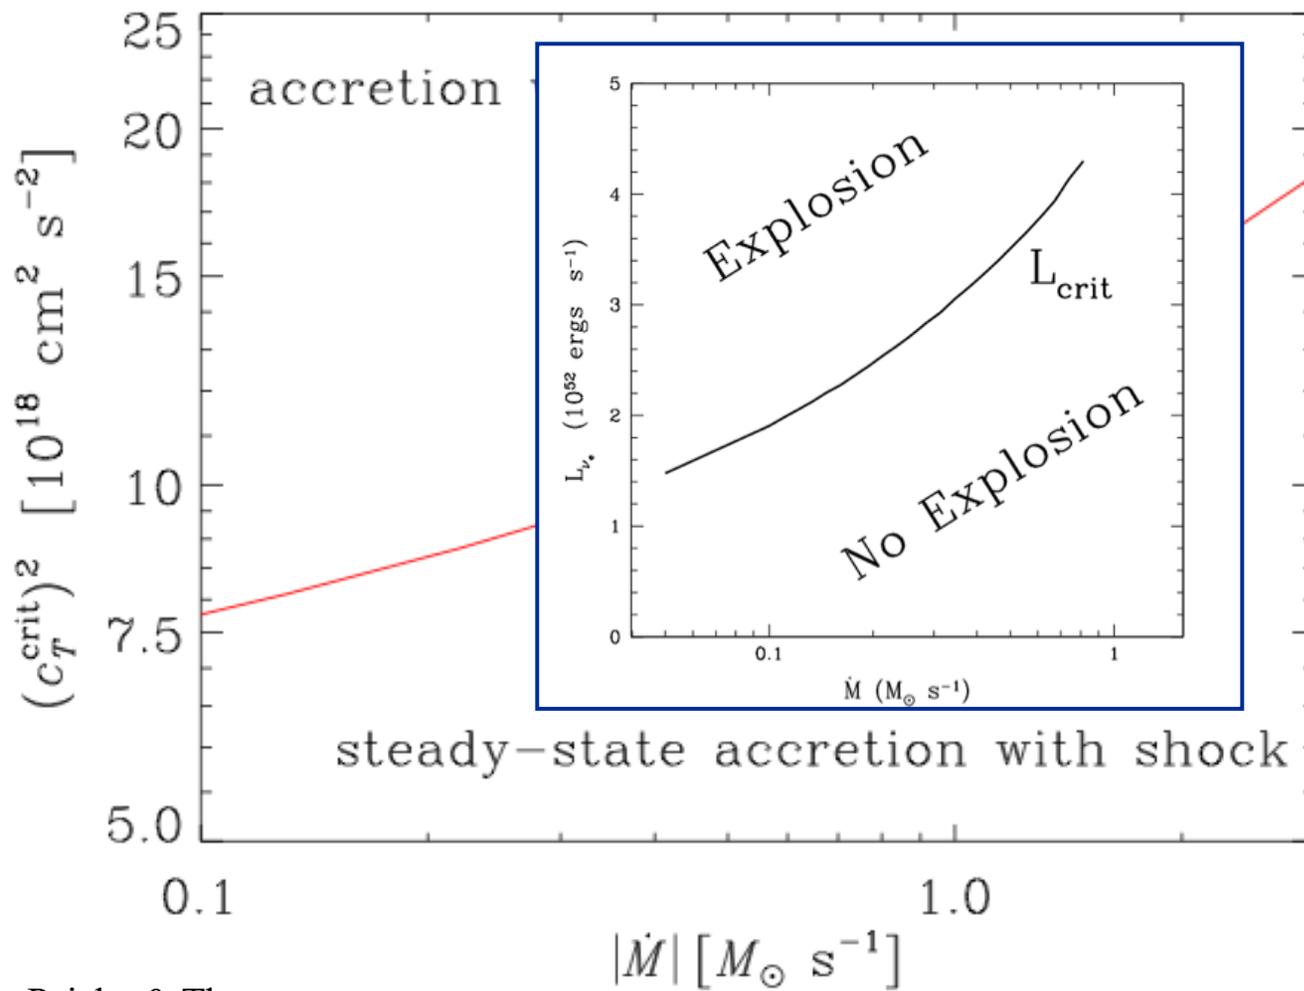

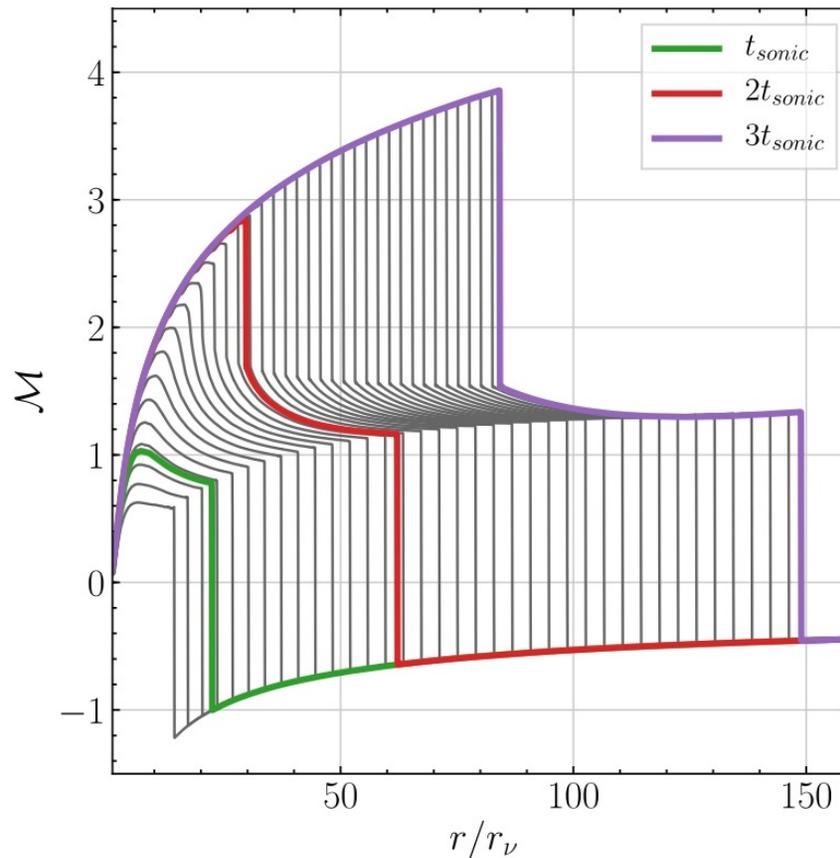

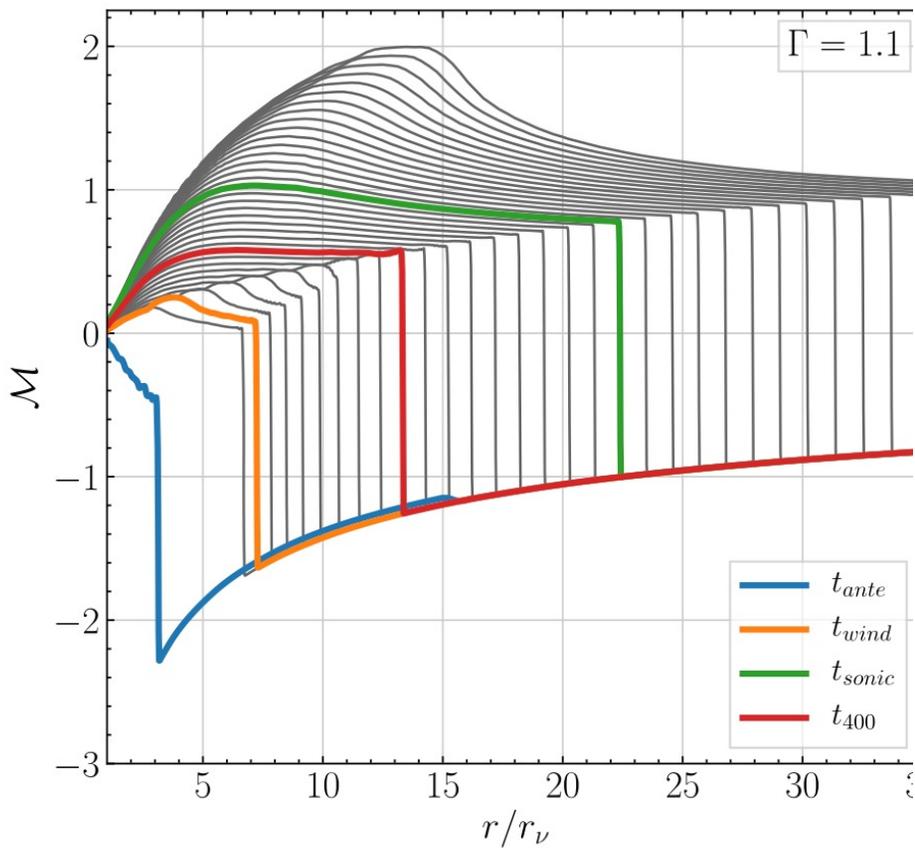

Pejcha & Thompson

Pejcha & Thompson

If exceeded, transition to wind-driven shell: “Explosion”

Raives et al. 2018; Pochik & Thompson 2025

Is the “antesonic” condition the answer?

Objection I: You need real physics.

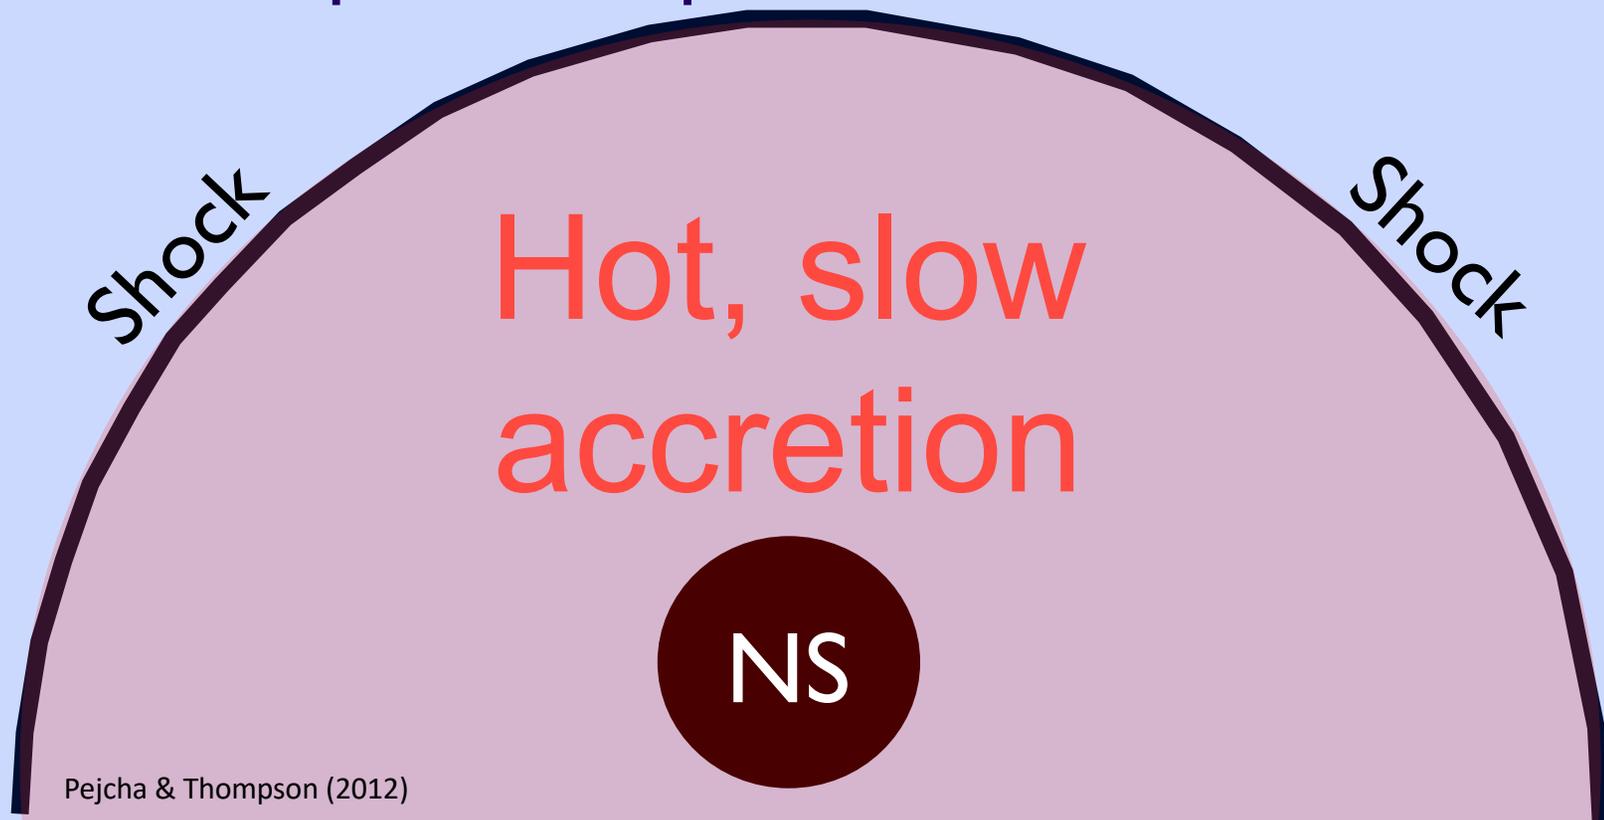

Response: In 1D models with real physics, condition unchanged. Ratio of c_s^2/V_{esc}^2 is \sim constant across exploding models (Pochik & Thompson 2025).

Objection II: Normalization of L_{crit} is lower in 2D and 3D. Why?

Response: Many ideas. There might be a simple extension of this idea (Raives+2021, 2026, in prep).

Why are supernovae “close” to exploding?

Cold supersonic pressure-less free fall

Pejcha & Thompson (2012)

Why are supernovae “close” to explosion?

Shock heating. As material lands on the shock, it thermalizes its gravitational binding energy. For a shock at some radius corresponding to V_{esc} :

$$\text{Shock heating: } \frac{c_s^2}{V_{\text{esc}}^2} = \frac{2\gamma(\gamma - 1)}{(\gamma + 1)^2} = \frac{8}{49} \approx 0.16 \quad (\gamma = \frac{4}{3})$$

$$\text{Critical value "Antesonic": } \frac{c_s^2}{V_{\text{esc}}^2} = \frac{3\gamma}{16} = \frac{1}{4} = 0.25 \quad (\gamma = \frac{4}{3})$$

Why do supernovae explode?

Hypothesis: “Antesonic” condition: $c_s^2/V_{\text{esc}}^2 = 3\gamma/16$.

→ Above this limit, it is impossible to simultaneously satisfy the shock jump conditions and the time-steady Euler equation at any radius. If exceeded, the system transitions to a thermal wind.

Why are supernovae “close” to explosion?

Shock-heating: $c_s^2/V_{\text{esc}}^2 = 2\gamma(\gamma-1)/(\gamma+1)^2$.

For $\gamma = 4/3$ this is 0.65 of c_s^2/V_{esc}^2 and 0.81 of c_s/V_{esc} required for explosion.

→ Supernovae are marginal because the specific thermal energy of the matter falling onto the shock and the specific thermal energy required for explosion are both approximately V_{esc}^2 .

(Bonus question: What about $\gamma = 5/3$?)

Raives, Coughlin, Thompson 26, in prep
