We are interested in understanding universal aspects of strongly-interacting systems

 \rightarrow specifically in their real-time dynamics

understanding these has implications in high-energy, condensed matter, and quantum information

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > <

we'll focus on complexity in quantum mechanical systems

Complexity is a somewhat intuitive notion

The traditional definition involves building a circuit with gates drawn from a universal gate set, which implements the state or unitary to within some tolerance

We are interested in the minimal size of a circuit that achieves this

Complexity a panoply of references

we've heard a lot about complexity growth already in this workshop

e.g. talks by Rob Myers, Vijay Balasubramanian, and Thom Bohdanowicz; in talks later today/this week by Bartek Czech, Gabor Sarosi, Shira Chapman; and in many posters

and much progress has been made in studying complexity growth in holographic systems

[Susskind], [Stanford, Susskind], [Brown, Roberts, Susskind, Swingle, Zhao], [Susskind, Zhao], [Couch, Fischler, Nguyen], [Carmi, Myers, Rath], [Brown, Susskind], [Caputa, Magan], [Alishahiha], [Chapman, Marrochio, Myers], [Carmi, Chapman, Marrochio, Myers, Sugishita], [Caputa, Kundu, Miyaji, Takayanagi, Watanabe], [Brown, Susskind, Zhao], [Agón, Headrick, Swingle], ...

as well as extending definitions to understand a notion of complexity in QFT

[Chapman, Heller, Marrochio, Pastawski], [Jefferson, Myers], [Hackl, Myers], [Yang], [Chapman, Eisert, Hackl, Heller, Jefferson, Marrochio, Myers], [Guo, Hernandez, Myers, Ruan], ...

Complexity

some expectations

it is believed(/expected/conjectured) that the complexity of a simple initial state grows (possibly linearly) under the time-evolution by a chaotic Hamiltonian

saturating after an exponential time

computing the quantum complexity analytically is very hard (especially for a fixed chaotic H and $|\psi\rangle$)

・ロト ・ 母 ト ・ ヨ ト ・ ヨ ・ うへで

ightarrow we'll focus on ensembles of time-evolutions (RQCs)

Our goal

Consider random quantum circuits, a solvable model of chaotic dynamics

we take local RQCs on n qudits of local dimension q, with gates drawn randomly from a universal gate set G

▲ロト ▲帰ト ▲ヨト ▲ヨト 三日 - の々ぐ

and try to derive exact results for the growth of complexity

Overview

- Define complexity
- Complexity by design
- Complexity in local random circuits
- Solving random circuits
- (complexity from measurements)

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

State complexity

more serious version

Consider a system of n qudits with local dimension q, where $d=q^n$

Complexity of a state: the minimal size of a circuit that builds the state $|\psi\rangle$ from $|0\rangle$

We assume the circuits are built from elementary 2-local gates chosen from a universal gate set G. Let G_r denote the set of all circuits of size r.

Definition (δ -state complexity)

Fix $\delta\in[0,1],$ we say that a state $|\psi\rangle$ has $\delta\text{-complexity}$ of at most r if there exists a circuit $V\in G_r$ such that

$$\frac{1}{2} \left\| |\psi\rangle\!\langle\psi| - V |0\rangle\!\langle 0|V^{\dagger} \right\|_{1} \leq \delta \,,$$

which we denote as $C_{\delta}(|\psi\rangle) \leq r$.

Unitary complexity

more serious version

Consider a system of n qudits with local dimension q, where $d = q^n$

Complexity of a unitary: the minimal size of a circuit, built from a 2-local gates from G, that approximates the unitary U

Definition (δ -unitary complexity)

We say that a unitary $U\in U(d)$ has $\delta\text{-complexity}$ of at most r if there exists a circuit $V\in G_r$ such that

$$\frac{1}{2} \left\| \mathcal{U} - \mathcal{V} \right\|_{\diamond} \le \delta$$

where $\mathcal{U} = U(
ho) U^\dagger$ and $\mathcal{V} = V(
ho) V^\dagger$,

which we denote as $\mathcal{C}_{\delta}(U) \leq r$.

Complexity by design

We start with some general statements about the complexity of unitary k-designs

related ideas were presented in $_{[{\sf Roberts},\ {\sf Yoshida}]}$ relating the frame potential to the average complexity of an ensemble

But first, we need to define the notion of a unitary design

Unitary k-designs

Haar: (unique L/R invariant) measure on the unitary group U(d)

The k-fold channel, with respect to the Haar measure, of an operator $\mathcal O$ acting on $\mathcal H^{\otimes k}$ is

$$\Phi_{\text{Haar}}^{(k)}(\mathcal{O}) \equiv \int_{\text{Haar}} dU \, U^{\otimes k}(\mathcal{O}) U^{\dagger \otimes k}$$

For an ensemble of unitaries $\mathcal{E} = \{p_i, U_i\}$, the *k*-fold channel of an operator \mathcal{O} acting on $\mathcal{H}^{\otimes k}$ is

$$\Phi_{\mathcal{E}}^{(k)}(\mathcal{O}) \equiv \sum_{i} p_{i} U_{i}^{\otimes k}(\mathcal{O}) U_{i}^{\dagger \otimes k}$$

An ensemble of unitaries \mathcal{E} is an exact k-design if

$$\Phi_{\mathcal{E}}^{(k)}(\mathcal{O}) = \Phi_{\text{Haar}}^{(k)}(\mathcal{O})$$

e.g. k = 1 and Paulis, k = 2, 3 and the Clifford group

Unitary k-designs

Haar: (unique L/R invariant) measure on the unitary group U(d)k-fold channel: $\Phi_{\mathcal{E}}^{(k)}(\mathcal{O}) \equiv \sum_{i} p_{i}U_{i}^{\otimes k}(\mathcal{O})U_{i}^{\dagger \otimes k}$ exact k-design: $\Phi_{\mathcal{E}}^{(k)}(\mathcal{O}) = \Phi_{\text{Haar}}^{(k)}(\mathcal{O})$

but for general k, few exact constructions are known

Definition (Approximate *k*-design)

For $\epsilon > 0$, an ensemble \mathcal{E} is an ϵ -approximate k-design if the k-fold channel obeys

$$\left\|\Phi_{\mathcal{E}}^{(k)} - \Phi_{\text{Haar}}^{(k)}\right\|_{\diamond} \le \epsilon$$

 \rightarrow designs are powerful

Intuition for *k*-designs (eschewing rigor)

How random is the time-evolution of a system compared to the full unitary group U(d)?

Consider an ensemble of time-evolutions at a fixed time t: $\mathcal{E}_t = \{U_t\}$ e.g. RQCs, Brownian circuits, or $\{e^{-iHt}, H \in \mathcal{E}_H\}$ generated by disordered Hamiltonians

quantify randomness: when does \mathcal{E}_t form a *k*-design? (approximating moments of U(d))

Complexity by design

an exercise in enumeration

Consider a discrete approximate unitary design $\mathcal{E} = \{p_i, U_i\}.$

Can we say anything about the complexity of U_i 's?

The structure of a design is sufficiently restrictive, can **count** the number of unitaries of a specific complexity

Theorem (Complexity for unitary designs)

For $\delta > 0$, an ϵ -approximate unitary k-design contains at least

$$M \ge \frac{d^{2k}}{k!} \frac{1}{(1+\epsilon')} - \frac{n^r |G|^r}{(1-\delta^2)^k}$$

unitaries U with $C_{\delta}(U) > r$.

This is essentially $\approx (d^2/k)^k$ for $r \lesssim kn$ (exp growth in design k)

Random quantum circuits

Consider G-local RQCs on n qudits of local dimension q, evolved with staggered layers of 2-site unitaries, each drawn randomly from a universal gate set G

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ のQ@

where evolution to time t is given by $U_t = U^{(t)} \dots U^{(1)}$

RQCs and randomness

Now we need a powerful result from [Brandão, Harrow, Horodecki]

Theorem (G-local random circuits form approximate designs)

For $\epsilon > 0$, the set of all G-local random quantum circuits of size T forms an ϵ -approximate unitary k-design if

 $T \ge cn \lceil \log k \rceil^2 k^{10} (n + \log(1/\epsilon))$

where c is a (potentially large) constant depending on the universal gate set G.

Less rigorous version: RQCs of size $T \sim n^2 k^{10}$ form k-designs

Complexity by design

curbing collisions

Now we can combine these two results to say something about the complexity of states generated by *G*-local random circuits

Fix some initial state $|\psi_0\rangle$, and consider the set of states generated by G-local RQCs: $\{U_i | \psi_0\rangle, U_i \in \mathcal{E}_{G\text{-local RQC}}\}$

Obviously, at early times: $C_{\delta}(|\psi\rangle) \approx T$

but we must account for collisions: $U_1 \ket{\psi_0} \approx U_2 \ket{\psi_0}$

and collisions must dominate at exponential times as the complexity saturates

but the definition of an $\epsilon\text{-approximate}$ design restricts the number of potential collisions

 \rightarrow allows us to count the # of distinct states

Complexity by design

curbing collisions

Now we can combine these two results to say something about the complexity of states generated by *G*-local random circuits

Fix some initial state $|\psi_0\rangle$, and consider the set of states generated by *G*-local RQCs: $\{U_i | \psi_0\rangle, U_i \in \mathcal{E}_{G\text{-local RQC}}\}$

For $r \leq \sqrt{d},$ G-local RQCs of size T, where $T \geq c \, n^2 (r/n)^{10},$ generate at least

$$M \gtrsim c' e^{r \log n}$$

distinct states with $C_{\delta}(|\psi\rangle) > r$.

This establishes a polynomial relation between the growth of complexity and size of the circuit up to $r \leq \sqrt{d}$

 \rightarrow but what we really want is linear growth

To get a linear growth in complexity we need a linear growth in design

we had $T = O(n^2 k^{10})$, but would need $T = O(n^2 k)$

[Brandão, Harrow, Horodecki]: a lower bound on the k-design depth for RQCs is O(nk)

Can we prove that RQCs saturate this lower bound? (and are thus optimal implementations of k-designs)

I'll now briefly summarize the result mentioned two weeks ago

using an exact stat-mech mapping, we can show that RQCs form k-designs in O(nk) depth in the limit of large local dimension

this was for local Haar-random gates, but we believe it should extend to G-local circuits with any local dimension q

Random quantum circuits

Consider local RQCs on n qudits of local dimension q, evolved with staggered layers of 2-site unitaries, each drawn randomly from the Haar measure on $U(q^2)$

where evolution to time t is given by $U_t = U^{(t)} \dots U^{(1)}$

Study the convergence of random quantum circuits to **unitary** k-designs, i.e. depth where we start approximating moments of the unitary group

Our approach

- Focus on 2-norm and analytically compute the frame potential for random quantum circuits
- Making use of the ideas in [Nahum, Vijay, Haah], [Zhou, Nahum], we can write the frame potential as a lattice partition function
- We can compute the k = 2 frame potential exactly, but for general k we must sacrifice some precision
- We'll see that the decay to Haar-randomness can be understood in terms of domain walls in the lattice model

Frame potential

The frame potential is a tractable measure of Haar randomness, defined for an ensemble of unitaries \mathcal{E} as [Gross, Audenaert, Eisert], [Scott]

$$k$$
-th frame potential : $\mathcal{F}_{\mathcal{E}}^{(k)} = \int_{U,V\in\mathcal{E}} dU dV \left| \operatorname{Tr}(U^{\dagger}V) \right|^{2k}$

For any ensemble $\ensuremath{\mathcal{E}}$, the frame potential is lower bounded as

$$\mathcal{F}^{(k)}_{\mathcal{E}} \geq \mathcal{F}^{(k)}_{ ext{Haar}}$$
 and $\mathcal{F}^{(k)}_{ ext{Haar}} = k!$ (for $k \leq d$)

with = if and only if \mathcal{E} is a k-design.

Related to ϵ -approximate k-design as

$$\left\| \Phi_{\mathcal{E}}^{(k)} - \Phi_{\text{Haar}}^{(k)} \right\|_{\diamond}^{2} \leq d^{2k} \left(\mathcal{F}_{\mathcal{E}}^{(k)} - \mathcal{F}_{\text{Haar}}^{(k)} \right)$$

Frame potential for RQCs

The goal is to compute the FP for RQCs evolved to time *t*:

$$\mathcal{F}_{\mathrm{RQC}}^{(k)} = \int_{U_t, V_t \in \mathrm{RQC}} dU dV \left| \mathrm{Tr}(U_t^{\dagger} V_t) \right|^{2k}$$

Consider the k-th moments of RQCs, k copies of the circuit and its conjugate:

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

Lattice mappings for RQCs

Haar averaging the 2-site unitaries allows us to exactly write the frame potential as a partition function on a triangular lattice.

The result is then that we can write the k-th frame potential as

with $\sigma \in S_k$, width $n_g = \lfloor n/2 \rfloor$, depth 2(t-1), and pbc in time.

The plaquettes are functions of three $\sigma \in S_k$, written explicitly as

$$J_{\sigma_{2}\sigma_{3}}^{\sigma_{1}} = \sigma_{1} \sigma_{3} = \sum_{\tau \in S_{k}} \mathcal{W}g(\sigma_{1}^{-1}\tau, q^{2})q^{\ell(\tau^{-1}\sigma_{2})}q^{\ell(\tau^{-1}\sigma_{3})}$$

Lattice mappings for RQCs

Haar averaging the 2-site unitaries allows us to exactly write the frame potential as a partition function on a triangular lattice.

The result is then that we can write the *k*-th frame potential as

$$\mathcal{F}_{\mathrm{RQC}}^{(k)} = \sum_{\{\sigma\}} \prod_{\triangleleft} J_{\sigma_2 \sigma_3}^{\sigma_1} = \sum_{\{\sigma\}}$$

with $\sigma \in S_k$, width $n_g = \lfloor n/2 \rfloor$, depth 2(t-1), and pbc in time.

We can show that $J_{\sigma\sigma}^{\sigma} = 1$, and thus the minimal Haar value of the frame potential comes from the k! ground states of the lattice model

$$\mathcal{F}_{\mathrm{RQC}}^{(k)} = k! + \dots$$

RQC domain walls

all non-zero contributions to $\mathcal{F}_{\mathrm{RQC}}^{(k)}$ are domain walls (which must wrap the circuit)

e.g. for k = 2 we have

configuration:

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 のへぐ

k-designs from domain walls

To compute the k-design time, we simply need to count the domain wall configurations

$$\mathcal{F}_{\mathrm{RQC}}^{(k)} = k! \left(1 + \sum_{1 \text{ dw}} wt(q, t) + \sum_{2 \text{ dw}} wt(q, t) + \dots \right)$$

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 の�?

 \rightarrow decay to Haar-randomness from dws

RQC 2-design time

We have the k = 2 frame potential for random circuits

$$\begin{split} \mathcal{F}_{\mathrm{RQC}}^{(2)} &\leq 2 \bigg(1 + \bigg(\frac{2q}{q^2 + 1} \bigg)^{2(t-1)} \bigg)^{n_g - 1} \\ \text{and recalling that } \big\| \Phi_{\mathrm{RQC}}^{(2)} - \Phi_{\mathrm{Haar}}^{(2)} \big\|_{\diamond}^2 &\leq d^4 \big(\mathcal{F}_{\mathrm{RQC}}^{(2)} - \mathcal{F}_{\mathrm{Haar}}^{(2)} \big), \end{split}$$

the circuit depth at which we form an ϵ -approximate 2-design is then

$$t_2 \ge C(2n\log q + \log n + \log 1/\epsilon)$$
 with $C = \left(\log \frac{q^2 + 1}{2q}\right)^{-1}$

and where for q=2 we have $t_2\approx 6.2n,$ and in the limit $q\rightarrow\infty$ we find $t_2\approx 2n$

$k\text{-}\mathsf{designs}$ in RQCs

For general k, we then have the contribution from the ground states and single domain wall sector, plus higher order contributions

$$\mathcal{F}_{\rm RQC}^{(k)} \le k! \left(1 + (n_g - 1) \binom{k}{2} \binom{2(t-1)}{t-1} \left(\frac{q}{q^2 + 1} \right)^{2(t-1)} + \dots \right)$$

(ロ)、(型)、(E)、(E)、 E) の(の)

k-designs in RQCs

For general k, we then have the contribution from the ground states and single domain wall sector, plus higher order contributions

$$\mathcal{F}_{\text{RQC}}^{(k)} \le k! \left(1 + (n_g - 1) \binom{k}{2} \binom{2(t-1)}{t-1} \left(\frac{q}{q^2 + 1} \right)^{2(t-1)} + \dots \right)$$

Moreover, the multi-domain wall terms are heavily suppressed and higher order interactions are subleading in $1/q\ {\rm as}$

$$\sim \frac{1}{q^p}$$

In the large q limit, the single domain wall sector gives the ϵ -approximate k-design time: $t_k \geq C(2nk\log q + k\log k + \log(1/\epsilon))$, which is

$$t_k = O(nk)$$

・ロト ・西ト ・ヨト ・ヨー うらぐ

RQCs form k-designs in O(nk) depth

we showed this in the large \boldsymbol{q} limit, but this limit is likely not necessary

Conjecture: The single domain wall sector of the lattice partition function dominates the multi-domain wall sectors for higher moments k and any local dimension q.

As the lower bound on the design depth is O(nk), RQCs are then **optimal implementations of randomness**

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > <

Back to complexity

We'll now end on a much more speculative note

If this result holds for G-local random circuits, and for any local dimension q, then the circuits of size $T = O(n^2k)$ form approx unitary k-designs

Therefore, G-local RQCs of size T generate at least $M \ge (d/k)^k$ distinct states with complexity $C_{\delta}(|\psi\rangle) \approx T$. For $k \le \sqrt{d}$, we have

$$M \gtrsim e^{T \log n}$$

This would then realize a conjecture by [Brown, Susskind] in an explicit example:

the # of states with $C_{\delta}(U_T |\psi_0\rangle) \approx T$, generated by time-evolution to time T (in this case RQCs of size T), scales exponentially in T

Future science

- ► Can we prove anything about $C_{\delta}(e^{-iHt} |\psi\rangle)$ for a fixed Hamiltonian?
- ► Can we rigorously bound the higher order terms in *F*^(k)_{RQC} at small *q*? and then extend the result to *G*-local RQCs
- Explore the implications of an operational definition of complexity (in terms of a distinguishing measurement). More suited for holography?

Thanks!
