Important elements and atomic properties

Small number of valence electrons

- Small number of transitions
→ higher transition probability (sum rule)
- Low-lying energy levels
→ higher electron population

$$\tau_l = \frac{\pi e^2}{m_e c} n_{i,j} t \lambda_l \frac{g_k f_l}{g_0} e^{-\frac{E_k}{kT}}$$

Systematic investigation of strength of lines

1. Collect the data of bound transitions for Ra II, Ac III, Th III
2. Calculate Sobolev optical depths (under LTE)

$$\tau_l = \frac{\pi e^2}{m_e c} n_{i,j} t \lambda_l \frac{g_k f_l}{g_0} e^{-\frac{E_k}{kT}}$$

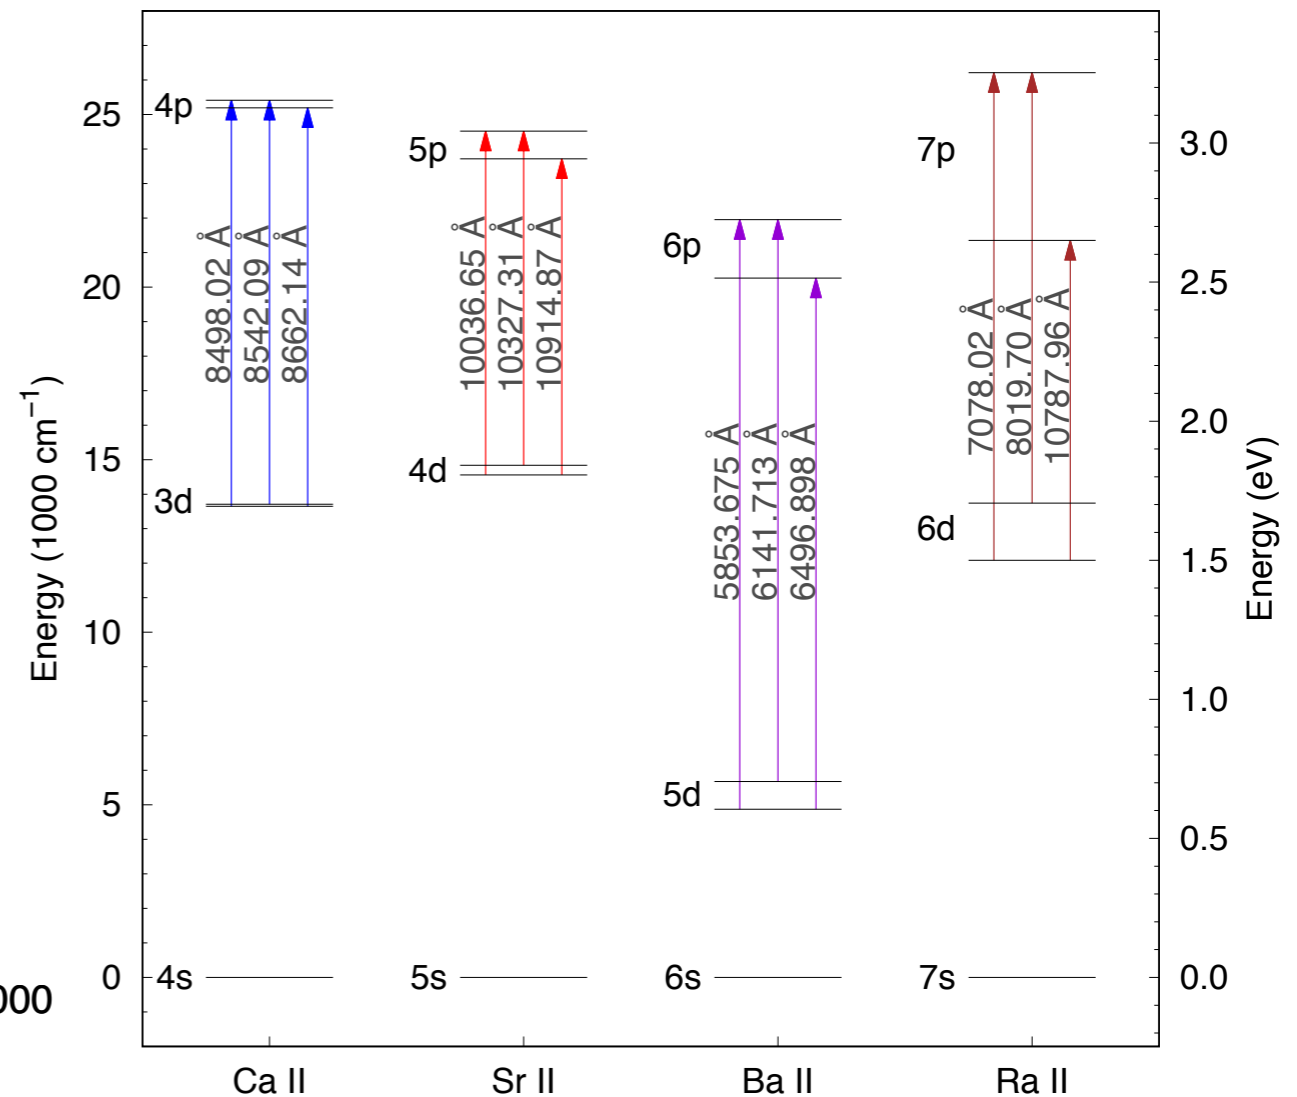

$\rho = 10^{-14} \text{ g cm}^{-3}$, $T = 5000 \text{ K}$ at $t=1.5 \text{ d}$

※Blue model reasonably explains La III/Ce III features in AT2017gfo

Ra II (Z=88) is not promising

Analogous atomic structure/transitions to Ca II, Sr II

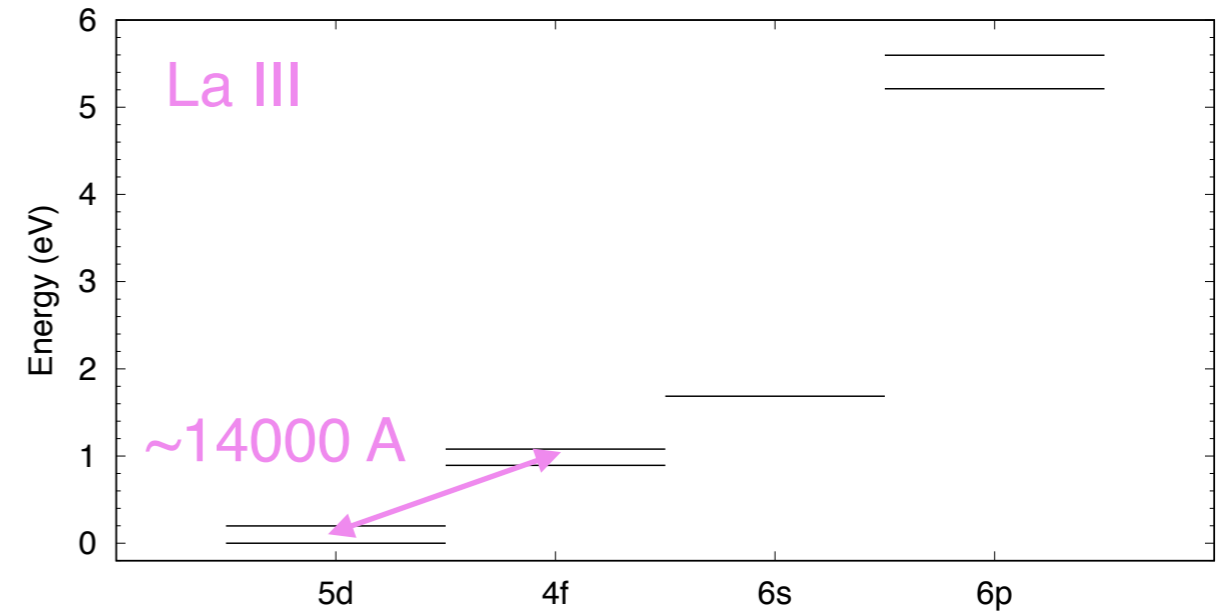

Mass fraction of Ra $\sim 10^{-5} \leftrightarrow$ Ca, Sr $\sim 10^{-2}$

Ra II lines cannot compete with lines of lanthanides w/ similar mass fractions

Ac III (Z=89) is not promising

NOT analogous atomic structure/transitions to La III

Ac III does not have NIR (E1) lines from low energy levels

Th III (Z=90) is the most promising

Dense low-lying energy levels (compared to Ce III)

$\rho = 10^{-14} \text{ g cm}^{-3}, T = 5000 \text{ K}$ at $t=1.5 \text{ d}$

Th III can produce strong transitions (comparable to e.g., Ce III)

Synthetic spectra

Perform radiative transfer simulations

*1D density structure ($\rho \propto r^{-3}$)

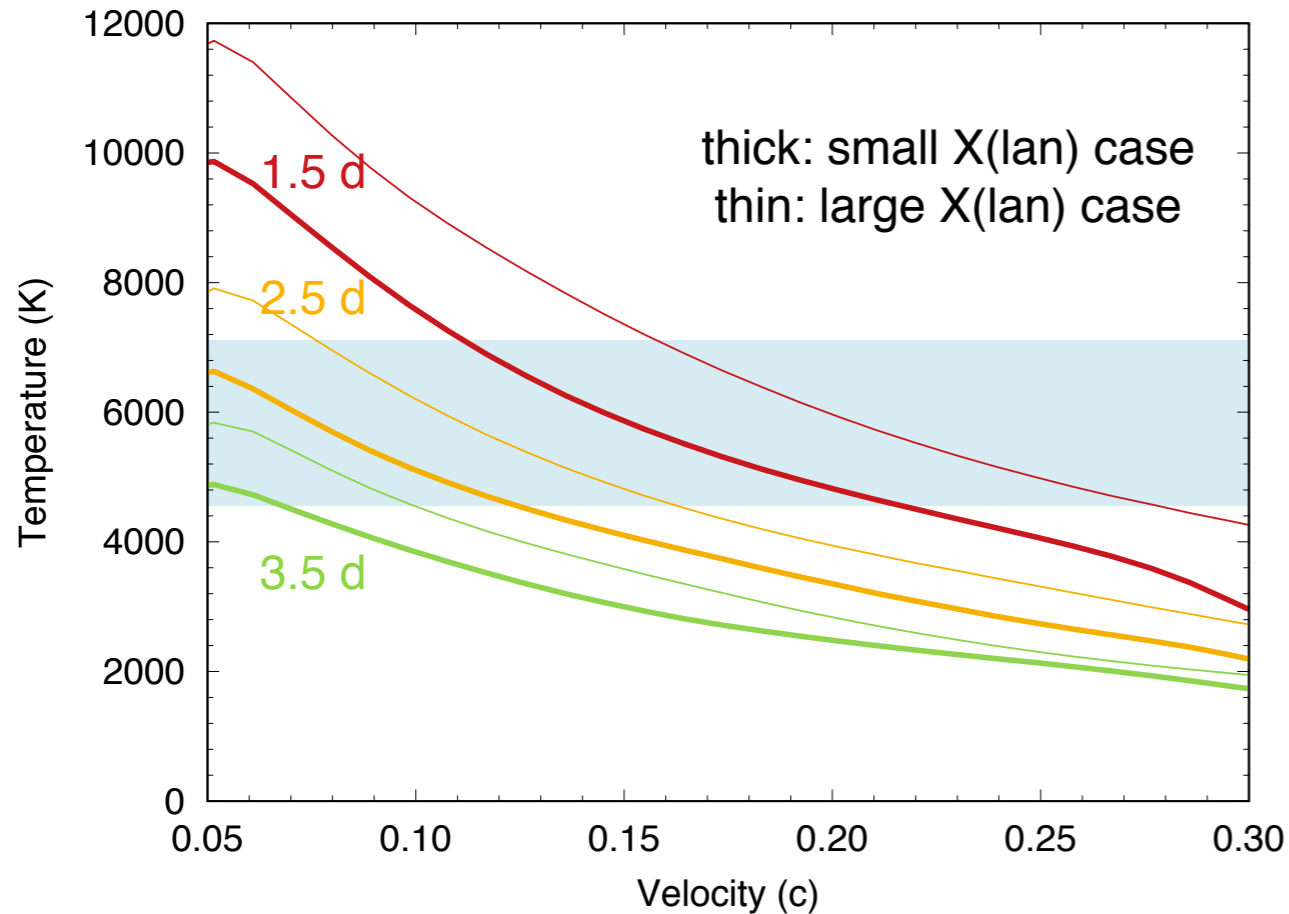

line forming region: $T \sim 7000 \text{ K}$ ($v=0.13c$)

$T \sim 3700 \text{ K}$ ($v=0.37c$)

Temperature dependence of Th III lines

Larger amount of lanthanides (w/ homogeneous abundance distribution)

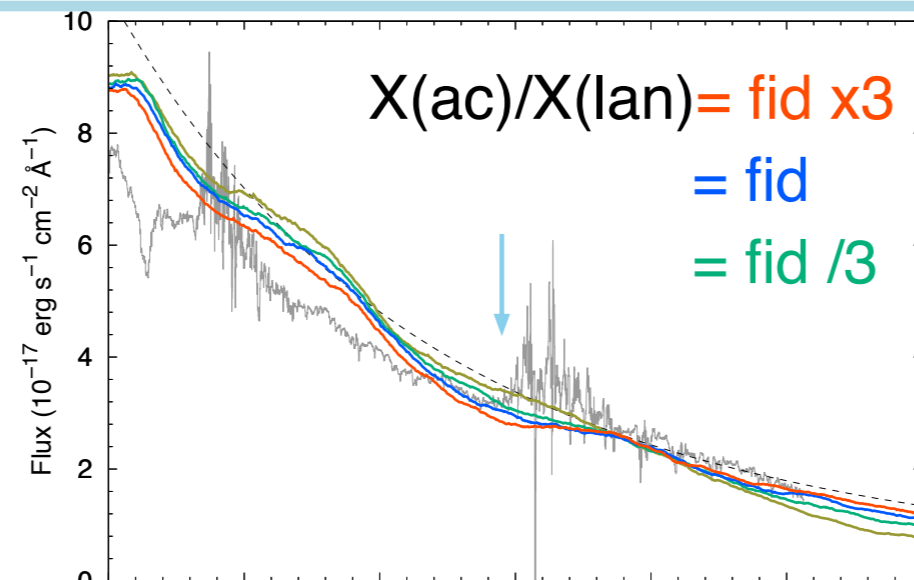

→ high opacity

→ photosphere goes outward where T is lower

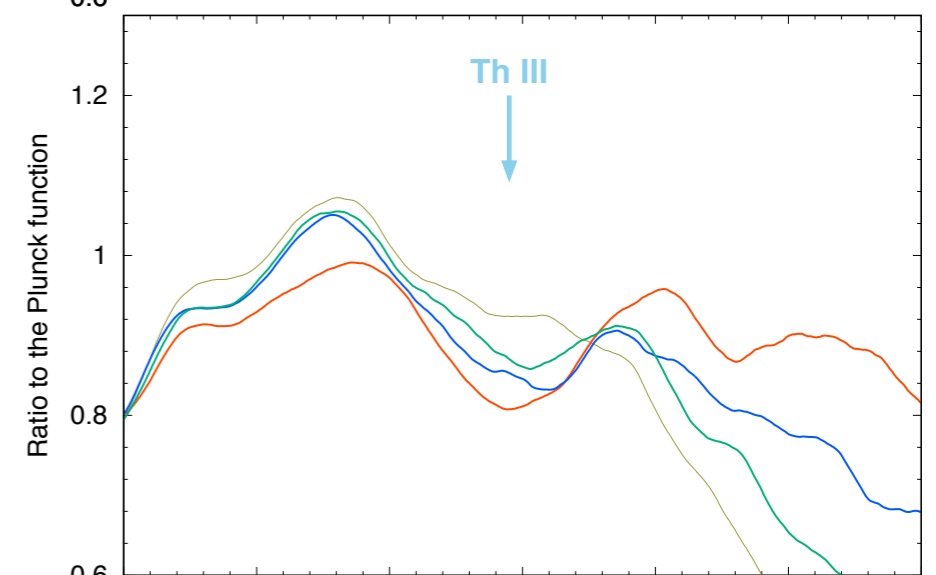

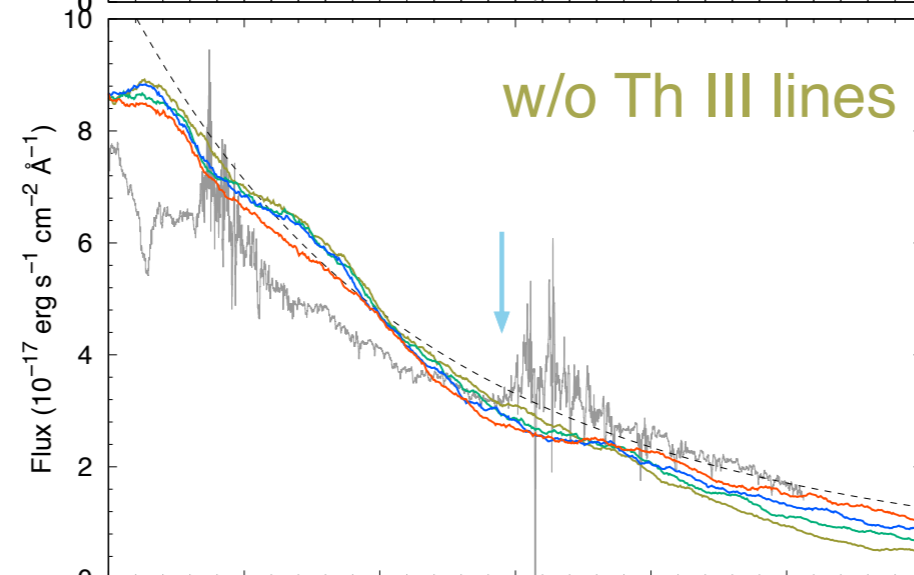

※ The feature would be even stronger if the condition that photospheric T=5000-7000 K w/ a larger mass fraction of lanthanides and Th were realized

Conditions to find Th features *homogeneous abundance distribution

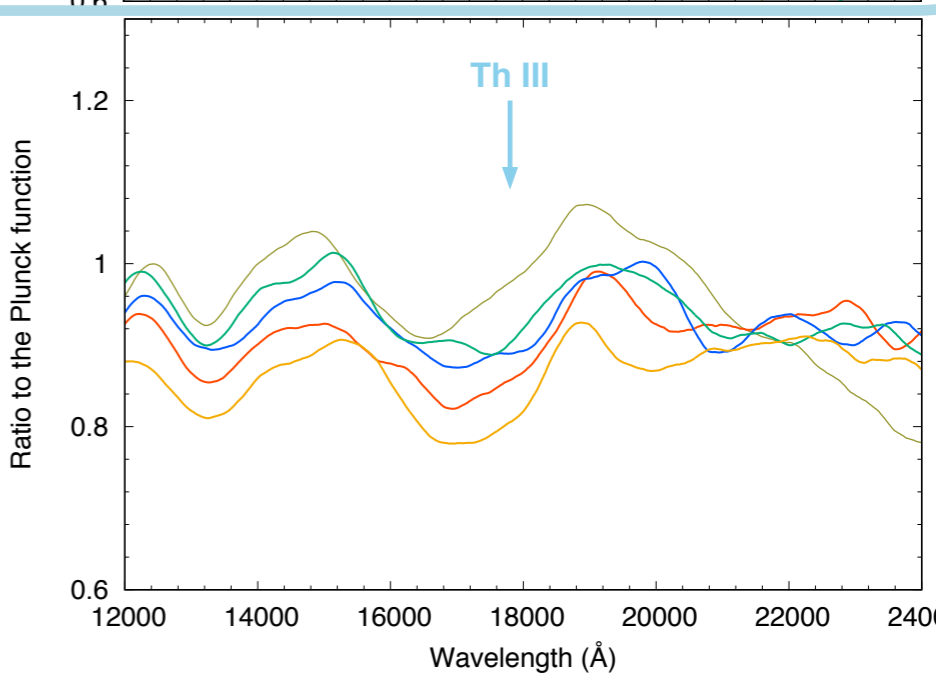

$X(\text{lan}) = \text{fiducial}$
 $\sim 6 \times 10^{-4}$

$X(\text{lan}) = \text{fid} / 3$

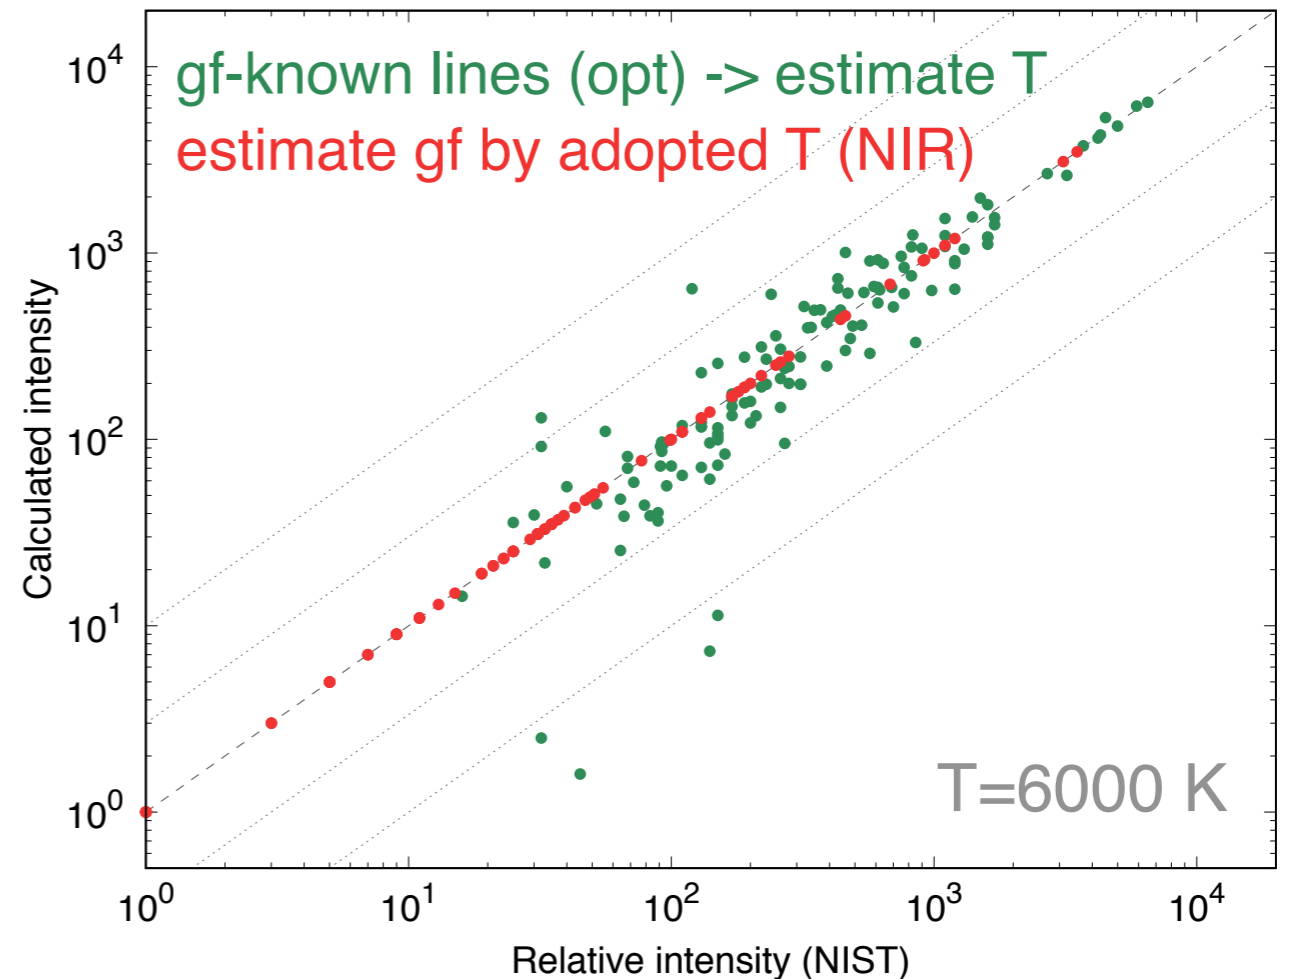

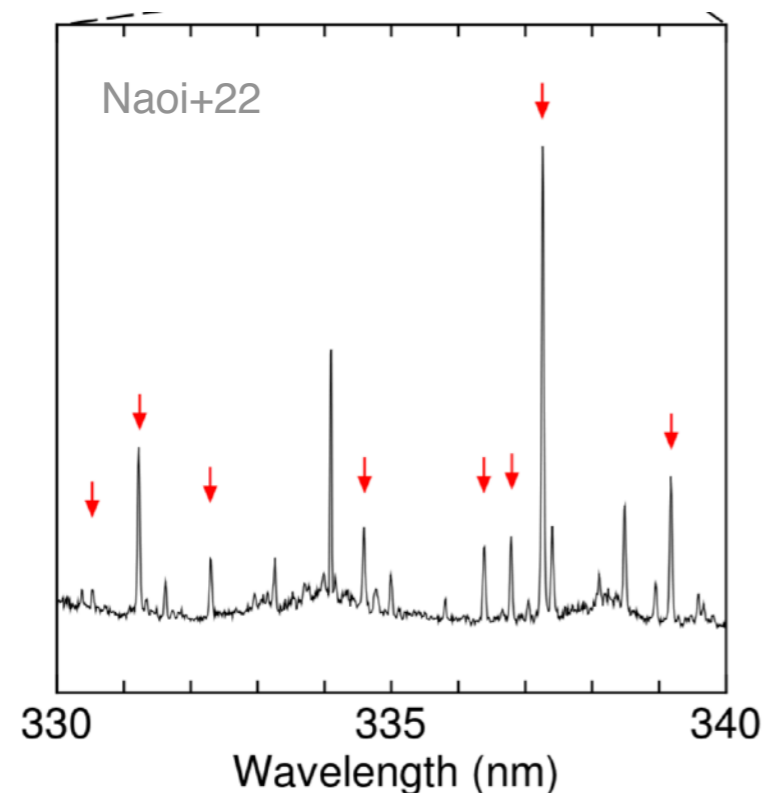

$X(\text{lan}) = \text{fid} \times 3$

Uncertainties in Th features

Transition probabilities of NIR lines are estimated by “relative intensities”

$$I \propto \frac{8\pi e^2}{m_e c \lambda^2} gf e^{-\frac{E_u}{kT}}$$

Should be derived by experiments, or provided by serious theoretical calculations

Summary

Th is the most promising candidate to find in the kilonova spectra ($\sim 1.8 \mu\text{m}$)

- Dense energy levels and relatively large transition probabilities
- Could be indirect evidence of production of Pt, Au

Condition

- $X(\text{lan}) < \sim 6 \times 10^{-4}$: bulk of high- Y_e (> 0.3) ejecta
w/ a small fraction of neutron-rich component in the line-forming region
- BH-NS or unequal mass BNS?

Observation

- Should be done with no or little atmosphere... from space or high-altitude sites

Uncertainties

- Transition probabilities of NIR Th III lines should be determined by experiments
